v. 10
CP 2

Journal of the Society of Chemical Industry.

INDEX OF VOL. X.—1891.

INDEX OF AUTHORS' NAMES.

N.B.—In this Index, (P) indicates that the matter referred to is an abstract of a Patent.

A

	PAGE		PAGE
Abney, Capt. Colour Measurement and Mixture.....	390	Armstrong, J. H., Engines for making Paper Pulp (P).....	62
Colour-Photometry.....	1031	Antonshevic, J., Analysis of Russian Waxes.....	1014
Grease-Spot Photometer Measures.....	18	Appian, G., System of Continuous-acting Kilns (P).....	141
Actien Gesellschaft fur Anilin Fabrikation. Manufacture of		Applegarth, E., Treating Fibrous Materials for Manufacture	
Colouring Matters (P).....	558	of Paper, &c. (P).....	768
Aeworth, J. J., Manufacture of Photographic Films (P).....	793	Arata, P., and Gelzer, C., Morresine and Morrenol.....	819
Adam, G., See Ladenburg.....	818	Archbutt, L., Discussion on Treatment of Hard Water, 517, 518,	519
Adams, C., Reduction of Metallic Ores (illus.) (P).....	144	and Deeley, R. M., The Treatment of Hard Water.....	511
Addie, R., The Siemens Furnace.....	934	Arlt, O., Filters and Filtering Materials (P).....	684
Adeney, W. E., Purification of Sewage and Recovery of		Armour, H., See Rowan.....	680
Ammonia (P).....	1021	Armour, L. H., Means for Manufacture of Hard Coke, &c. (P)	627
Adkins, W., See Muller.....	245	Armstrong, H. E., and Pope, W. J., Studies of the Terpenes	
Aerated Fuel Co., The, Apparatus for Burning Liquid Hydro-		and Allied Compounds.....	653
carbons (P).....	824	Armstrong, H. E., and Rissler, E. C., Action of Nitric Acid	
Ahrens, F. B., Sparteine.....	568	on Naphthol Derivatives. Formation of Nitro-keto	
Aignan, Condition of Tartaric Acid in Aqueous Solutions.....	724	Compounds.....	693
Akester, W. H., Frosting Glass Globes (P).....	368	Preparing Nitro-derivatives, and Use of Nitrogen Dioxide	
Alberti and Hempel, Determination of the Ash of Sugar.....	1039	as a Nitrating Agent.....	691
Allen, A. H., Discussion on Estimation of Glycerin.....	204	Armstrong, H. E., and Wynne, W. P., Constitution of Tri-	
Discussion on Incandescent Gas Lighting.....	200	derivatives of Naphthalene, No. 9.....	248
Discussion on the Constitution of Butter.....	42	Armstrong, L. D., Apparatus for Recovering Soda, &c., from	
Discussion on the Chemistry of Whisky.....	314, 521	Spent Liquors (P).....	463
Discussion on Treatment of Hard Water.....	517, 518	Arnand, A., See Grimaux.....	723, 850
Discussion on Volumetric Estimation of Alumina.....	263	Arnaudon, S. S., Tanning Woods.....	55
Further Notes on the Chemistry of Whisky.....	519	Arndt, F. M., Ipecacuanha and Emetin.....	488
The Chemistry of Whisky and Allied Products.....	395	Arnold, P., Apparatus for Drying Clay Products (P).....	368
Allen, E. W., and Tollens, B., On Wood Sugar and Wood		Arnold, T., Manufacture of Cement (P).....	1008
Gum.....	473	Arnott, G. W., Olivier, P. A., and Seagrave, G., Washing Wool,	
On Xylonic Acid.....	473	&c. (P).....	134
Allen, J. F., Manufacture of Illuminating Gas (P).....	396	Arsonval, A. d', Use of Liquid Carbonic Acid for Rapid Fil-	
Almond, T. R., Flexible Tubing (illus.).....	35	tration and Sterilisation of Organic Liquids.....	717
Amat, L., Analysis of Hypophosphorous, Phosphorous, and		Asbóth, A. von., Production of Sugar in Austria-Hungary in	
Hypophosphoric Acids.....	68	1889-90.....	174
Amsterdamsche Chininefabrik, Production of Anthranilic		The Iron Industry of Hungary.....	806
Acid (P).....	831	The Metal Industry of Hungary.....	806
Amthor, C., Addition of Sugar and Water to Acid Wine.....	591	Aschan, O., Acids of Low Carbon Percentage in Baku Petro-	
Anderlini, F., Cantharidin.....	244	leum.....	997
Andersch, H., Guttman's Improvements in the Manufacture		Asenuth, J., Manufacture of Sodium Borate and other	
of Nitric Acid.....	45	Sodium or Boron Compounds (P).....	1006
Anderson, E. W., Apparatus for Cutting Smokeless, Explosive,		Ashley, H. M., Manufacture of Ceramic Ware (P).....	148
or other Plastic Material into Lengths (P).....	161	Askham, P. W., and Wilson, W., Electro-Magnetic Separators	
Anderson, H. A., See Page.....	776	for Extracting Metal from Slag (P).....	706
Anderson, W. F., Discussion on Cyanide Gold Extraction		Reducing or Disintegrating Apparatus (P).....	749
Process.....	96	Astfalek, A., See Schmeller.....	554
Discussion on Incandescent Gas Lighting.....	200	Atkins, C. H., See Rising.....	847
Discussion on Tanning by Electricity.....	431	Anders, G. L., and Elliot, C. H., Application of Xylonite,	
Andiran, A. J. J. d', See Durand.....	359	Celluloid, &c. (P).....	380
Andiran-Koechlin, A. J. J. d', See Durand.....	539	Auer, Discussion on Use of Calcium Sulphhydrate in Alkali	
André, G., Compounds of Mercuric Chloride.....	724	Manufacture.....	220
Preparation and Reactions of Mercury Ammonium		Auer, C., See Stenger.....	561
Chlorides.....	638	Auguste-Godechaux, P., Apparatus for Printing in Colours (P)	766
See Bertuclet.....	711, 715	Ayrton, Lamb, Smith, and Robertson, The Chemistry of	
André, G. G., See Curtis.....	855	Secondary Cells.....	572
Andresen, M., Constitution of Organic Photographic Devel-		Automatic Filter Co., The Filters, and Means for Cleansing	
opers.....	982	Filtering Surfaces (P).....	823
		Avenarius, R., See Link.....	571

	PAGE		PAGE
B		Beale, H. H. Scarlet Liquid for Treating Photographic Negatives (P).....	159
Badecek, H., Gransell, W., and Walker, A. Prevention of Polarisation in Batteries (P).....	136	Beam, W. See Leffmann.....	864
Badische Anilin und Soda Fabrik. Manufacture of Substantive Dyestuffs (P).....	578	Beatson, W. Recovering Tin from Waste Tinned Iron or Steel (P).....	706
Manufacture of Sulpho-Acids of Red Basic Naphthalene Colouring Matter (P).....	831	Beck, Discussion on Home-Grown Sugar.....	327
Manufacture of Trioxylbenzophenone (P).....	538	Beck, L. B. Manufacture of Manila Paper (P).....	268
Production of Amido-Azo Compounds and Azo Dyes therefrom (P).....	760	Beck, R. and Lutz, W. Formation of Graphite by Contact Metamorphosis.....	863
Production of a New Naphthalene Derivative (P).....	762	Becker, H. Cutting Glass Tubes (P).....	139
Production of Artificial Indigo, &c. (P).....	634	Beckmann, B. J. Manufacture of Paper, Pasteboard, &c. (P).....	944
Production of a Sulpho-Acid suitable for Dyeing and Printing (P).....	820	Behrens, G. B. and Watson, J. C. Preparation of "Wash Greys" (P).....	924
Production of Blue Basic Dyestuff (P).....	762	Beilby, G. Discussion on Manufacture of Phosphorus.....	447
Production of Colouring Matters from Dihydroxybenzoic Acid (P).....	759	Discussion on the Nitrogen of Crude Petroleum and Paraffin Oils.....	121
Production of Diphenyl Derivatives and a New Base (P).....	759	The Nitrogen of Crude Petroleum and Paraffin Oils.....	120
Production of Materials for Preparation of Dyestuffs (P).....	759	Belcher, H. Treatment of Skins or Hides (P).....	780
Production of Substantive Colouring Matters (P).....	249	Bell, C. R. E. Manufacture of Matches (P).....	574
Production of Substantive Dyestuffs (P).....	760	Bell, G. See Vivian.....	610
Production of Sulpho-Acids of a Red Basic Naphthalene Colouring Matter (P).....	459	Bell, J. Carter. Discussion on Application of Magnesia Cement.....	114
Sulpho-Acids of Red Basic Naphthalene Dyestuff (P).....	831	Bell, R. The Nickel and Copper Deposits of Sudbury, Canada.....	372
Treating Alizarin Blue to obtain New Compounds thereof and Alizarin Blue S (P).....	358	Bell, Sir Lowthian. Speech at Inaugural Dinner of Yorkshire Section.....	903
Baznall, J. See Mackintosh and Co., Ltd.....	713	Bellamy, C. H. Machines for Marbling Paper, &c. (P).....	924
Bailey, G. H. Rapid Gravimetric Analysis (illus.).....	329	Bellerstein, B. Carbonisers for Destroying Vegetable Matter mixed with Wool (P).....	918
Baird, A. and M. B. See Turner.....	645	Beloe, C. H., and Candy, F. Cleansing Filters and Filtering Material (P).....	1021
Baker, W. J. Apparatus for Filtering Water (P).....	625	Benardis, N. de, and others. Secondary Batteries (P).....	554
Bahagny, G. Flexible Phototype Plates (P).....	572	Bender. Effect of Cooling on the Viscosity of Oils.....	936
Baldensperger, T. Ingray-Black from Diamine-Black.....	762	Benedikt, R., and Bamberger, M. Determination of Mechanical Wood Pulp in Paper.....	576
Baldwin, W. A. Alloying Metals (P).....	776	Benedikt, R., and Mangold, K. On Hubb's Method for Examination of Wax.....	860
Bale, F., and Sons, T. C. Manufacture of Peroxide of Hydrogen (P).....	482	Bender. On the Imperfect Solubility of Mineral Oils in Petroleum Spirit.....	354
Ballard. Action of Meat Extracts on Certain Metals.....	379	Berg, M. J. Production of Aluminium (P).....	553
Ballantyne, H. Discussion on Effect of Exposure on Constants of Oils.....	38	Berger, J. The Manufacture of Rice Starch.....	152, 781
Effect of Exposure on some Constants of Oils.....	29	Bergh, A. See Joergensen.....	378
See Thomson.....	293	Bergreen, R. Knife for Slicing Sugar-Beets and Canes (P).....	154
Ballard, F. G. Ascertaining Required Time of Exposure in Photography (P).....	159	Bermer, G. Bromoform.....	791
Balli, B. Determination of Acid Tartrate in Wine Lees.....	862	Bermer, G. M. What is Aristol, and how is it Manufactured?.....	569
Ballingall, D. See Robertson.....	821	Berkel, A. von. Magnesia Cement.....	771
Baly, E. C. C. Mercury Vacuum Pumps (illus.) (P).....	1032	Berliner Aethenische Gesellschaft vorm. Freund & Co. Pneumatic Maltng Drums (P).....	940
Bamberger, E. The Constitution of 5-Membered Ring Systems.....	828	Bernbeck. A Simple Test for Tar Products in Ammonia.....	164
Bamberger, E., and Wulz, P. Homologues of Tetrahydroquinoline.....	999	Berthelot. Action of Heat on Carbonic Oxide.....	662
M-thyl-para-toluidine.....	1000	A Reaction of Carbonic Oxide.....	662
Tetra-hydro-ortho-hamidopinaldine.....	999	On the Persulphates.....	836
Bamberger, M. See Benedikt.....	576	Report on Fixation of Nitrogen by Electricity.....	498
Baptista, J. Manufacture of Soap (P).....	709	Berthelot and Andre, G. Humus.....	711
Preparation of Paint Oils (P).....	846	Berthelot and Andre. Nitrogenous Constituent of Soils.....	715
Baraoglu, G. A., and Marquardt, A. Action of Sulphur on Benzaldehyde.....	829	Berthelot, D. The Preparation of the Explosive Waxe in Liquids and Solids.....	384
Barber, S. Method and Apparatus for Continuous Distilling (P).....	629	Berthelot, M. Condensation of Acetylene by Silent Electric Discharge.....	40
Barker, G. F. The Border Land between Physics and Chemistry.....	730	Berton, C. I. C. Recovery of Tin from Sheet Clippings, &c. (P).....	775
Barnes, W. H. Compositions to be used as Paints (P).....	150	Bertrand, G. Derivatives of Xylose.....	710
Barnett, D. Extracting Oil and Grease from Cotton Waste (P).....	134	Bertschinger, A. The Examination of Beer.....	274
Barotte, H. Production of Dry Extract of Coffee (P).....	266	Besina, C. Estimation of Free Acids in Butter.....	800
Barrett, A. A. Concentrated Essential Oils of Lemons, Limes, &c.....	106	Best, L. C. Apparatus to Facilitate Fining of Beer (P).....	651
Discussion on Concentrated Essential Oils.....	108	Best, T. T. Discussion on Use of Calcium Sulphhydrate in Alkali Manufacture.....	220
Bar, R. See Mills.....	265	Bentle, C. See Von Gmiesch.....	841
Bartel, A. Estimation of Tannins in Acid Liquors.....	823	Bevan, E. J. Discussion on Volumetric Estimation of Alumina.....	203, 317
Bartolf, A. Utilising Waste Chips, &c., of Rhubarb Root (P).....	656	See Cross.....	202, 786, 831
Bartholomew, C. W., and Oxley, J. Apparatus for Drawing Coke from Ovens (P).....	688	Beveridge, J. Manufacture of Pearl Hardening (P).....	787
Barlow, W. Utilising Leather Waste (P).....	558	Beyer, A. and A. Apparatus for Crushing and Moulding Toilet Soap (P).....	148
Bartram, G. H. Source of Error in Determination of Nitrates in Water.....	951	Beyhkey, M. W., and others. Alkaline Magnesium Compound (P).....	768
Baswitz, C. Rendering Textiles Waterproof and Non-Combustible (P).....	133	Bidet, A. Simultaneous Action of Air and Light on Organic Compounds.....	693
Batalle, J. Improving Wine and Alcoholic Liquors (P).....	562	Biedermann, A., and Lepetit, R. Indigo Synthesis from Amido-acetic Acid.....	41
Batehlor, T. C. See Butlerfield.....	1029	Biedermann, R. Chemiker-Kalender, 1892.....	950
Bates, H., jun. Corn Product for Brewers' Use (P).....	154	Technisch-chemisches Jahrbuch, 1889-1890.....	72
Bateson, Percy. Fuel Purification.....	984	Biernacki, E. Capacity of Antiseptics to hasten Alcoholic Fermentation.....	783
Bath, P. A. Utilising Scoria of Copper-Smelting Furnaces (P).....	1011	Bielski, E. Polishing Compositions (P).....	264
Bandin, E. Detection of Rosin Oil in Oil of Turpentine.....	800	Billing, C. Manufacture of Soap (P).....	148
Baudouin, H., and Escarpit, P. Manufacture of Ammonia (P).....	640	Bilmmann, O. Producing Coloured Designs on Glass (P).....	548
Bauleh, J. Blacking for Leather (P).....	1016	Biltz, H. See Brühl.....	568
Baumann, A. New Methods of Quantitative Analysis.....	799	Birch, W. Apparatus for Filtering Sewage, &c. (P).....	61
Baummann. Sugar Estimation with Fehling's Solution.....	168	Bischof, C. Slate-Chay in the Coal Measures of Bohemia.....	465
Baur, A. Studies on Artificial Musk.....	1024	Bischof, G. Manufacture of White Lead (P).....	841
Bayless, M. See Davies Bros. & Co.....	553		
Benham, F. C. D. Photographic Spotting or Re-touching (P).....	703		

	PAGE		PAGE
Bishop, A. See Gridley.....	625	Bradbury, R. H. See Smith.....	1037
Blair, A. A. Determination of Carbon in Steel.....	574	Braham, P. Pinch-cock for Regulating the Flow of Liquids and Gases (P).....	189
Blanc, G. See Sykes.....	353, 532	Brasch, R., and Freyss, G. Benzidine Dyes.....	915
Blank, A. Synthesis of Carbazole.....	356	Brash, R. Nitro-Derivatives of Alizarin and Purpurin.....	828
Blarez, C. Effect of Haloid Potassium Salts on Solubility of Potassium Sulphate (P).....	608	Braun. See Favre.....	697
Influence of Extractive Matters in Spirits on Density Determinations.....	609	See Schladenhaußen.....	954
Influence of Potassium Salts on Solubility of Potassium Bitartrate.....	717	Bray, S. T. J. Apparatus for Burning Liquid Fuel (P).....	626
The Solubility of Potassium Bitartrate.....	488	Breglia, L., and Breza, F. Preserving Articles of Food (P).....	477
Blas, E. See Fox.....	687	Brehier, A. U., and Talbot, E. G. Manufacture of Artificial Tartaric Acids (P).....	571
Blau, F. Constitution of Nicotine.....	567	Bretherick, J. W. Appliances for Manufacture of Paper (P).....	1022
Blenkinsop, W. E. B. See Hartley.....	263	Breza, F. See Breglia.....	477
Blount, Bertram. Discussion on Bituminous Coal.....	980	Bridgman, H. Le Roy. Ore Sampling Machines (illus.) (P).....	990
Discussion on Copper Smelting.....	14	Brinkley. Discussion on Incandescent Gas Lighting.....	200
Discussion on Cyanide Gold Extraction Process.....	98	Brin's Oxygen Co., Ltd., and Murray, K. S. Apparatus for Automatically Changing Direction of Flow of Currents through Pipes (P).....	529
Discussion on Chemical Changes between Nitric Acid and Metals.....	211	Brochocki, T. de. Manufacture of Anhydrous Barium Oxides (P).....	253
Discussion on Gums.....	622	Brook, J., and Minton, T. Filter-Presses (P).....	127
Discussion on Products of Incomplete Combustion.....	415	Brookway, W. L. Treating Waste Tinned Steel or Iron (P).....	704
Discussion on Volumetric Estimation of Alumina.....	203	Brodbeck, C. Imparting a Silky Appearance to Fabrics, &c. (P).....	540
Experiments on the Cyanide Process for the Extraction of Gold.....	35	Brook, E. Improvements in Kilns (P).....	548
Blount, C. S., and others. Transparent Cloisonne Enamel (P).....	770	Brooke, Simpson, and Spiller, Ltd., and A. G. Green. Production of New Azo-Colouring Matters (P).....	633
Bloxam, A. G. Discussion on Chemical Changes between Nitric Acid and Metals.....	211	Brooks, J. B. Photographic Baths for Developing (P).....	572
Blum, J. Production of Water-Gas (P).....	626	Brough, B. H. Outbursts of Gas in Metalliferous Mines.....	113
Blum, L. Volumetric Method of Estimating Manganese.....	798	Browett, T. See Lindley.....	242
Boake, A. Discussion on Gums.....	622	Brown, C. A. Furnaces for Burning Refuse (P).....	239
See Giles.....	767	Brown, H. T., and others. Preparing Amylaceous Substances for Mashing (P).....	562
Boeddinghaus, W. On <i>p</i> -Nitrosobenzylaniline and Toluene.....	829	Amylols applicable for Treatment of Beer (P).....	265
Boehme, Comparative Examination of Puzzolana, Portland, and Roman Cements.....	140	Brown, J. Campbell. Discussion on Electrolytic Qualitative Analysis.....	328
Boehringer, C. F. Manufacture of Pyrazolones (P).....	792	Discussion on Home-grown Sugar.....	326
Boenig, E. See Walter.....	1007	Brown, R. C. See Fletcher.....	255
Boettcher, K. E. Secondary Element (P).....	554	Brownlow, R. S. Apparatus for Treating Water (P).....	128
Boettinger, C. On the Oxidation of Gallic Acid.....	480	Brubacher, R. See Goldschmidt.....	916
Böhm, M. Distilling Crude Petroleum, &c. (P).....	456	Bruck, H. Artificial Marble (P).....	614
Böhm, W. D. Separating Gold and Silver from Ores, &c. (P).....	645, 936	Bruhl, J. W. Investigations on the Terpenes and their Derivatives.....	1025
Separation of Gold from Ores, &c. (P).....	935	Bruhl, J. W., and Biltz, H. Alcohols.....	568
Bokelund, J. F. A. Substitute for Linseed Oil (P).....	714	Brüllé, R. Detection of Adulteration of Olive Oil.....	320
Bollmann, F. Malting Apparatus (P).....	844	Testing Olive Oils, Seed Oils and Butter.....	320
Bolton, E. Distilling and Condensing Apparatus (P).....	240	Brunn, A. Manufacture of Yeast (P).....	949
Borax Co., Ltd., The. Treating Borates of Lime and Boracite (P).....	597	Brunner, A. See Moschek.....	794
Bornträger, H. A Test for Resorcinol and for Thymol.....	167	Brunner, Dr. Discussion on Turkey-Red Oil.....	29
Gayon's Test for Aldehyde.....	575	Brunner, J. T. On the Inspection of Chemical Works.....	637
Borsche, G. The Stassfurt Potash Salts Industry during 1889.....	582	Bruns, A. Production of Sparkling Wines, &c. (P).....	1019
Bothamley, G. H. Some Recent Advances in Photography.....	523	Brunton, T. L., and Macfadyen, A. The Ferment Action of Bacteria.....	730
Bott, J. E. Mortimore, W., and Lindley, F. H. Gas Producers (P).....	627	Brush, C. B. Works for the Automatic Supply of Bone at Syracuse, U.S.	462
Böttger, E. Diazo- and Hydrazine Compounds of the Quinoline Bases.....	998	Buchanan, J. Precipitating Gold or Silver (P).....	261
Böttger, P. Manufacture of Colouring Matters (P).....	131, 759	Buchka, K., and Magelhaens, A. Cytisine.....	388, 508
Bottom, T. D. Manufacture of Insulating Compositions (P).....	555	Buehner, G. Arsenic in Commercial Acids.....	460
Bottomley, J. Intensity of Transmitted Light.....	730	Buckland, W. H., and G. Meyers. Composition and Manufacture of Fuel from Coal Dust (P).....	688
Boulet, G., Fils, Donard and Contamine. Apparatus for Extraction of Fats, Sulphur, &c. (P).....	683	Budden, E. R. Maturing Wines, &c. (P).....	843
See Donard.....	908	Budd, J. Utilising Mineral Colours on Glass and Metal (P).....	699
Boullanger, D. A., and Scheunert, A. Purifying Alcoholic Liquors (P).....	562	Budenberg, W. Sterilising Milk, &c. (P).....	719
Boulton, W. Machinery for Manufacture of Pottery Ware (P).....	110	Buffet, E. Electrical Batteries (P).....	706
Bourgougnon, A. See Mandel.....	855	Buisine, A., and P. Adulteration and Analysis of Bees'-Wax.....	729
Bourquelot, E. Saccharine Bodies in Fungi.....	56	The Bleaching of Bees'-Wax and the Composition of White Wax.....	52
Bovey, V. See Dollfus.....	563	The Composition of Bees'-Wax.....	52
Bowden, J. A. Filtering apparatus (P).....	822	Theory of Bleaching by Exposure to Air.....	707
Filters (P).....	822	Bull, J. C. Refining Copper (P).....	935
Bower, H., and Pemberton, H., jun. Report on Consumption of Distilled Spirits in the Arts, Manufactures, and Medicine in the United States.....	170	Bunte, H. The Valuation of Coal.....	359

INDEX OF SUBJECTS.

N.B.—In this Index (P) indicates that the matter referred to is an abstract of a patent: (T.R.) indicates that the matter referred to is in the Trade Report.

	PAGE		PAGE
A		Aldehyde, Gayon's Test for. (Borotraget)	575
Alchemoschus esculentus	250	Aldehydes, Pyrrol a Reagent for. (Hil)	165
Absorption Plates, Wood-Wool. (Camerer)	164	Aldephalutic Acid. (Wanklyn)	212
Accidents in Factories, Appliances for Prevention of. (Van Vleet)	126	Algarobilla, the Tannin Matters of. (Zoffel)	831
In Prussian Factories. (Chem. Ind.)	126	Alizarine, Application of, in Leather Dyeing. (Koechlin and Knecht)	234
Accumulators. See Batteries.		Alizarin Blue, Bisulphite Compounds of, as Sensitisers. (Higgs)	657
Acetic Acid, Production of. (P) Dudley	825	Blue, Hydroxy-Derivatives of. (Schmidt and Gattermann)	1003
Acid, Recovery of, in Manufacture of Charcoal. (P) Zwillingner	129	Blue, Obtaining New Compounds of, and Alizarin Blue S (P) Johnson. From The Badische Anilin und Soda Fabrik	358
Acetone, Estimation of, in Denatured Spirit. (Vignon)	630	Formation of Quinizarin from. (Grachet)	355
New Reagent for. (Schwicker)	861	Manufacture of New Derivatives of. (P) Willeox. From The Farb. vorm. Bayer and Co.	537
The Methods for Quantitative Estimation of. (Collischonn)	166	New Derivatives of. (P) Willeox. From The Farb. vorm. Bayer and Co.	917
Acetylthromprotocetone. (Cimminan and Silber)	1025	Nitro-Derivatives of. (Brashi)	828
Acetylene, Condensation of, by Silent Electric Discharge. (Berthelot)	40	Production of New Derivatives of. (P) Willeox. From The Farb. vorm. Bayer and Co.	759
Acetylhexanthone. (Herzig)	913	Sulphonic Acids. (Schmidt)	556
Acetylacetone. (Herzig)	913	Alkali as a By-Product of Manufacture of Phosphate of Lime. (P) Simpson	255
Acetylmitro-indazole. (Watt, Noetting, and Grandmougen)	652	Employment of Sulphuretted Hydrogen in Manufacture of. (P) Simpson	926
Acetyl Salol. (Knecht)	652	Estimation of Combined, in Soap. (Wilson)	953
Acid Sulphates, Production of. (P) Giles, Roberts, and Bouke	767	Estimation of Small Quantities of. (Mylius and Foerster)	856
Acids, Alkalis, and Salts. (Class VII.) 45, 136, 177, 253, 287, 363, 660, 541, 635, 687, 766, 835, 925, 1001		Industry, the German. (T.R.)	582
Aconitum Napellus, The Crystalline Alkaloid of. (Dunston and Ince)	477	-Making, Utilising By-Products of Mineral Oil Manufacture for. (Aeth and Schestopal)	366
Aeridine Orange. (Chem. Zeit.)	135	Manufacture in Russian. (T.R.)	45
Aerospines, Removing, from Malt. (P) Hirschler	265	Manufacture in Russian. (T.R.)	171
Address, Lists of changes of. 2 88, 181, 294, 496, 511, 496, 676, 748, 820, 882, 974		Use of Calcium Sulphhydrate in Manufacture of, by Haddock and Leith's Process. (Leith) (Ilus.)	214
The Presidential, at Dublin	600	Waste, Production of Sulphuretted Hydrogen from. (P) Davidson and Davis	643
To Manchester Section, Chairman's	894	Waste, Treating Ammonium Chloride with. (P) Leith	367
Adonin. (Tahara)	1023	Works Inspector, 27th Annual Report of the Chief	635
Aerated Waters. See Waters.		Alkaline Bases, Action of, on Solubility of Alkaline Salts. (Enzel)	836
Agave Mexicana, The	250	Carbamates, Manufacture of. (P) Haddock and Leith	641
Agave parvula	250	Sulphides as Insecticides. (Dubois)	842
Aromatic Liquors. (P) Thompson. From Hasbrouck	154	Alkali. (Class VII.) 45, 80, 136, 177, 253, 287, 363, 660, 541, 635, 697, 766, 835, 925, 1001	
Axidating Apparatus. (P) Bradbury and Colebrook	490	Alkaloid from Comm. Maculatum, a New. (Ladenburg and Adam)	848
Agitators for Still Chests. (P) Lake. From Currier	157	Mumium, a New. (Merck)	481
Air, Apparatus for Carbonetting. (P) Hargreaves, Seranton, and Porter	534	New, from the Seeds of Comm. Maculatum. (Merck)	481
Apparatus for Separating Oxygen and Nitrogen from. (P) Cryer	528	Alkaloids. (Class XX.) 63, 85, 157, 181, 298, 291, 380, 477, 667, 652, 723, 787, 847, 944, 1023	
Corks for Mixing Gas and. (P) Goshide	528	New, from Sidaadilla Seeds. (Merck)	481
Combustion of, by Combustion of Hummants. (Cramer)	354	O Belladonna, the. (Hessel)	158
Fastness of Dyed Colours to Light and. (Wischer)	634	Of Delphinium Staphisagria. (Stara Stojnow)	481
Obtaining Oxygen from Atmospheric. (P) Longest	270	The Acetone. (Dunstan and Ince)	477
Obtaining Oxygen from Atmospheric. (P) Parkinson	947	The Use of Ammonium Selenite as a Test for the. (Silva)	857
Of Large Cities, Analysis of. (Industries)	267	Alkyl Hydroxy-Derivatives of Dimethylamine. (Grimaux)	458
Producing Oxygen from Atmospheric. (P) Neave	384	Alkylphenylhydrazine, Production of Symmetric. (P) Murray. From The Farb. vorm. Meister, Lucius and Bruning	1027
Smelling Crude Fatty Substances by Means of Hal. (P) Wild	471	Alloy for Hermetically Closing Glass Tubes (P) Walter	646
Theory of Bleaching by Exposure to. (Gausner)	707	Obtaining a New Metallic. (P) Held	838
Thermometer. (Sabner) (Ilus.)	162	Alloys, Coating Metals with. (P) Thompson. From Chamer. Manufacture of Metals c. (P) Vaughan. From Weiller	704
And Light, Simultaneous Action of, on Organic Compounds. (Bidel)	693	New Metallic. (P) Martino	775
And other Gases, Apparatus for Mixing, Measuring, and Delivering. (P) Thompson. From Taylor	534	Of Nickel, Manufacture of. (P) Garner	1010
Alaska, the Wealth and Resources of. (T.R.)	498	Of Sodium and Lead. (Grosche and Wahl)	142
Albument, "Ash-free" Egg. (Harnack)	360	Almonds, Testing Oil of Bitter. (Merck)	487
Sizing Paper with Ammonium	847	Alum, Manufacture of Soda. (P) Spencer	253
Albuminoids of the Oak Kernel, The. (Osborne)	941	Alumina Carbon, Manufacture of. (Wolffbauer)	776
Alcohol, Calculating Yield of, from Starch Materials. (Donath)	843	Determination of, in Phosphates. (Jones)	387
Detection of Impurities contained in. (Mohler)	68	Manufacture of Hydrazine of. (P) Meyer	925
Imports of, by Sum. (T.R.)	664	The Volumetric Estimation of. (Ross and Bevan)	202
Manufacture of. (P) Gengard and Bedouin	562	Volumetric Estimation of. (Lancel)	314
Production of Wood. (P) Dudley	825	Aluminium. (Hunt)	644
Progress of Purification during Rectification of. (Mohler)	748	Alloys, and Manufacture thereof. (P) Johnson. From Langley	616
Rose's Method for the Estimation of. (Grundant)	761	Alloys, the Herapit Process of Smelting. (Dewey)	49
Alcoholates. (Brühl and Biltz)	568	Analysis of Ferro. (Ziegler)	388
Alcoholic Liquids, Treatment of. (P) Mills and Barr	265	And Copper, Alloys of. (Regelsberger)	1034
Alcohols, on the Origin of the Higher, contained in Fermented Liquors. (Laudel)	717	And its Alloys, the Analysis of Commercial. (Regelsberger)	950
		And its Alloys, Valuation of. (Regelsberger)	1033

	PAGE		PAGE
Aluminium, a New Use for	1010	Amsterdam, Exhibition of Appliances for Prevention of Accidents in Factories. (Van Vliet)	126
Determination of Metallic Aluminium in Commercial. (Regelsberger)	387	Amylaceous Materials, Saccharification of. (P) Carez and La Soc. Maltose	154
Effecting Electrolytic Deposition with. (P) Woble	776	Amyl Acetate Lamp, Behaviour of Impure Materials in the. (Von Heffner)	909
Electro-Metallurgy of. (Minet)	470	Amyloins, Manufacture of, for Treatment of Beer. (P) Brown, Morris, and Moritz	265
Estimation of, in Iron and Steel. (Carnot)	389	Amyrins, α - and β -. Their Ethers and Bromine Derivatives. (Vesterberg)	56
Fluoride, Preparation of. (P) Lindsay	926	Analysis, Application of Electrolysis to Qualitative. (Kohn). New Methods of Quantitative. (Baumann)	327 799
Manufacture and Industrial Value of. (Dagzer)	432	Rapid Method of Gravimetric. (Bailey and Cain) (illus.)	329
Manufacture of. (P) Meyer	1012	Analytical and Scientific Notes 71, 488, 578, 602, 730, 805, 863, 955, 1040 Apparatus	1062, 771, 792
Manufacture of, from Fluorides. (P) Lindsay	926	Chemistry. (Class XXIII.)	67, 86, 162, 271, 292, 386, 481, 574, 657, 725, 794, 855, 919, 1029
Method of Soldering to other Metals. (P) Thompson. From Land	262	Andresen's β -naphthylamine-disulphonic Acid. (Armstrong and Wynne)	248
Obtaining Alloys of, with other Metals. (P) Clark	259	Angola, New Tanning Product in. (T.R.)	281
Physical Properties of some Alloys of.	702	Anhydrogeraniol. (Semmler)	568
Plates, Manufacture of Coated. (P) Thompson. From Land	262	Anilido-acetic Acid, Synthesis of Indigo from. (Biedermann and Lepetit)	41
Production of. (P) Berg	553	Anilido-palmitic Acid, α -	648
Production of. (P) White	144	Aniline, New Compounds of, with Metallic Sulphites. (Deniges) Black. (Gutknecht)	692 130
Production of, in the United States. (T. R.)	736	Black, Dyeing or Printing in. (P) Thies and Cella	697
Production of Pure. (P) Schneller and Astafek	554	Black, Dyeing with. (Oesterr)	460
Quantitative Separation of. (Marchal and Wiernicki)	1064	Black Dyes, Fastness of. (Evans)	511
Salts, Estimation of Basicity of Solutions of. (Gerland)	25	Animal Products, Report on, by Italian Customs Laboratory	51
Soldering. (P) Page and Anderson	776	Animal Dinner, The	607
Tempering, &c., Castings and Alloys of. (P) Eyraud	49	Meeting, Proceedings of the Tenth	597
Amalgamator, An Improved. (P) Cook	646	Anthracoene, Preparation of, from Fatty Hydrocarbons. (P) Hlawaty and Friedmann	455
Amalgams, Electrolytic Determination of Metals as. (Vort- mann)	1036	Anthraxite, Discovery of, in Canada. (T.R.)	868
Amarylline and Belamarine. (Fragner)	847	Anthranilic Acid, Production of. (P) Imray. From the Am- sterdamse Chinine-fabrik	831
Amazon Valley, The Natural Products of the. (T.R.)	394	Anthraquinone, α - and β -Disulphonic Acids, Conversion of, into Flavopurpurin and Anthrapurpurin. (Schmidt)	536
America, Industrial Progress of the Southern States of. (T.R.) The Wood Pulp Trade of. (T.R.)	581 74	New Derivatives of. (P) Wilcox. From the Farb. vorm. P. Bayer and Co.	917 536
American Chemical Society, The. (T.R.)	807	Series, Colouring Matters of the. (Schmidt)	917
Amethylcamphenolsulphone, Antiseptic Properties of. (Cazenave and Rodet)	724	Anti-corrosive Composition for Metals. (P) Maxwell	714
Amidodiazurin, α -. (Brash)	828	Compounds. (P) Dejoue	557
Amido-anthrappurpurine, Black Colouring Matters from. (P) Imray. From The Farb. vorm. Meister, Lucius, and Birling	249	Anti-fouling Compounds. (P) Dejoue	1017
Amido-Azo Compounds, Production of, and Azo Dyes there- from. (P) Johnson. From The Badische Anilin und Soda Fab.	760	Antimony, Determination of, as an Amalgam. (Vortmann)	1036
Amidodiphenyl- α -disulphonic Acid. (Lamprecht)	620	In Nevada	1010
Amidoflavopurpurine, Black Colouring Matters from. (P) Imray. From The Farb. vorm. Meister, Lucius, and Birling	249	Mining in Portugal. (Vogel)	837
Amidomethyl- p -toluidine, α -. (Bauerger and Wulz)	1001	Mirrors, Distinction between Arsenical and. (Deniges)	272
Amidonaphthalenesulphonic Acid, On α - β -, and its Derivatives. (Cleve)	1002	Pentasulphide. (Wilm)	1035
Amidopalmitic Acid, α -	648	Separation and Estimation of. (Thiele)	857
Amidophenol, m -Nitro- p -, and its Derivatives. (Hahle)	691	Antipyrine and Iodine, Manufacture of Compound of. (P) Imray. From the Farb. vorm. Meister, Lucius, and Birling	1028
Amidophenylindoline. (Fischer and Hepp)	458	Valerianate. (Sochaczewski)	159
Amidonaphthol, Production of New Sulpho Acids of. (P) Wilcox. From the Farb. vorm. Bayer and Co.	760	Antiseptics and Disinfectants. (P) Hargreaves	61
Amido-naphthylsulphonic Acid, Manufacture of a New, and - Colouring Matters therefrom. (P) Pitt. From Cassella and Co.	918	Capacity of, to Hasten Alcoholic Fermentation. (Bier- nacki)	783
Amidopurpurin. (Brash)	828	Manufacture of. (P) Johnson. From Von Heyden	722
Amines, Colour Reactions of Aromatic. (Lauth)	589	Apparatus, Adaptation of Stoneware to Chemical. (Rix.) (illus.)	417
Ammonia, Action of, in Cotton. (Vignon)	624	Analytical.	162, 271, 292
Apparatus for Distillation of. (P) Meldrum	462	General. (Class I.)	34, 78, 121, 174, 238, 285, 349, 448, 528, 624, 683, 749, 821, 906, 988
Apparatus for Manufacture of Sulphate of. (P) Dempster Compounds of Mercuric Cyanide. (Varet)	767 697	Argentina, Pharmaceutical Preparations in. (T.R.)	1042
From Nitrogen of Oil Works Acid Sludge. (Redwood) (illus.)	108	Supplementary Customs Law of. (T.R.)	283
Heat of Evaporation of Liquid. (Von Strombeck)	1005	Aristol, What is it, and how Manufactured. (Beringer)	569
Manufacture of. (P) Lake. From Hennin	906	Arkansas, Production of Bauxite in. (T.R.)	394
Method and Apparatus for Manufacture of Compounds of. (P) Holcke (illus.)	531	Armour Plates, Recent Tests of Nickel Steel. (T.R.)	868
On some Constants of. (Von Strombeck)	637	Arsenic, Deposition of, as Amalgam. (Vortmann)	1037
Packages for Conveying Carbonate of. (P) Needham	642	Detection of, in Metallic Iron. (Sautermeister)	949
Process and Apparatus for Manufacture of. (P) Badonin and Escarpit	649	Direct Estimation of, in Minerals and Metals. (Clark)	444
Process for Manufacture of Soda-. (P) Ricard	462	In Commercial Acids. (Buchner)	460
Production of. (P) Haddan. From Lambilly	642	In Crude Acids.	575
Product on of Sulphate of. (P) Wise. From Grouven	45	In Phosphorus. (Hampe)	486
Production of Sulphate of, in 1888, 1889, and 1890	636	On the Detection of. (Thiele)	950
Process of Water Analysis. (Haines)	1007	Pentasulphide, Influence of Ammonium Hydrate on. (Le Roy and McKay)	855
Recovery of, from Sewage, &c. (P) Adney	1021	Sulphuretted Hydrogen, Free from. (Hampe)	484
Recovery of, in Manufacture of Charcoal. (P) Zwillingner	129	Arsenical Dyes, Import into Norway of Cotton Goods contain- ing. (T.R.)	43
Simple Test for Tar Products in. (Bernbeck)	164	Mirrors, Distinction between Antimony and. (Deniges)	272
Soda Waste, the Utilisation of.	766	Artificial Manures Adulteration Bill. (T.R.)	172
Ammonium Albumen, Sizing Paper with	847	Asafetida, The Ethered Oil of. (Semmler)	157, 382
Chloride in Potassium Salts. (Neimke)	836	Asbestos Discovery in Victoria	634
Chloride, Treating, with Alkali Waste. (P) Leith	367	Discovery of, in New South Wales. (T.R.)	498
Hydrate, Influence of, on Arsenic Pentasulphide. (Le Roy and McKay)	855	The Chemical Composition of. (Donald)	762
Manufacture of Nitrate of, &c. (P) Burghard	640	Aspergillin; a Pigment Analogous to Blood-Haematin. (Linos- sier.)	723
Nitrate, Separation of, and Sulphate or Chloride of Sodium or Potassium. (P) Roth	270	A Vegetable Haematin. (Linossier)	724
Persulphate. (Marshall)	1004	Asphalt, Artificial. (P) Smith. From Nielsen	259
Phosphate as a Manure. (Vogel)	1017	Artificial. (P) Williams	1008
Preparation of Nitrate of. (P) The Rohrnite Explosives Co. Roth and Orsman	270	Asphaltum. (Eng. and Mining J.)	40
Pyrosulphite. (Fock and Kluss)	138	In the United States. (Parker)	910
Sulphide, Preparation of. (Donath)	949	Production, Imports and Exports of United States	40
Salts, Agricultural Value of. (Wagner)	375		
Selenite, the Use of, as a Test for the Alkaloids. (Silva)	857		

	PAGE		PAGE
Assam, The Resources of. (T.R.)	867	Battery Cells, Plates, Elements, Solutions, &c.— <i>cont.</i>	
Auditors, Election of.	603	Electrodes for Secondary Batteries. (P) Lake. From	
Aurous Chloride, Preparation of. (Lowe)	482	Johnson and Holdridge.	147
Australia, The Iron Ores of. (T.R.)	283	Electrodes of Lead Wire. (P) Legay	706
Austria-Hungary, Production of Sugar in, during 1889–90.		Electrolytes for Primary Batteries. (P) Wright	706
(Von Aschoth)	171	Element, Secondary. (P) Boettcher	554
The Patent Laws of. (T.R.)	399	Elements, Dry. (Elektrisch. Zeits.)	373
Mineral Production of, in 1890. (T.R.)	867	Elements for Voltaic Batteries. (P) Fitzgerald and Hough	51
Avenarius, Carlolinium. (Filsinger)	771	Elements, Manufacture of Secondary Battery. (P)	
Atlas Accumulator, The. (Elec. Rev.)	470	Stevenson	374
Azo-Colours. See Colouring Matters.		Galvanic Dry Elements. (P) Smith	1012
Azo-imide, Behaviour of, with Living Organisms. (Loew)	1024	Plates for Accumulators. (P) Cheswright	553
Azoniun Bases. (Kehrmann and Messinger)	999	Plates for Secondary Batteries. (P) Beckerzaun	51
Bases. (Witt)	827	Solution of Composition for Charging Electric. (P) Clark	777
Azotoline. (Fischer and Hepp)	458	Zinc for Galvanic. (P) Mosley	554
Azoxyamines, Colouring Matters Derived from. (P) Imray.		Baume and Cartier Degrees, Conversion of. (Mandel and	
Fr. in La Soc. Anon. des Matieres Colorantes.	633	Bourgoignon)	855
Manufacture of Azo-colouring Matters Derived from. (P)		Bauxite, Production of, in Arkansas. (T.R.)	391
Imray. From La Soc. Anon. des Matieres Colorantes.		Beer, Apparatus for Aeration of. (P) Sharp	265
A. F. Porrier and D. A. Rosenfeld.	358	Apparatus to Facilitate the Fining of. (P) Best	651
		Bacteria Occurring in. (Zeidler)	154
		Detection of Salicylic Acid in. (Pinette)	165
		Beer, Fermenting Process for. (P) Salmon	378
		Improvements in Brewing. (P) Cox	910
		In the Philippine Islands.	73
		Manufacture of Ammonia for Treatment of. (P) Brown,	
		Morris, and Moritz	265
		Manufacture of, from Maize.	719
		On the Examination of. (Bertschinger)	274
		Preparation for Fining and Frothing. (P) Reule	651
		Production of Non-Alcoholic. (P) Hoff	719
		Rousing. (P) Littleton	265
		Testing the Keeping Power of. (Van Laere)	782
		Treatment and Storage of. (Hartley)	57
		Bees-wax, Adulteration and Analysis of. (Buisine)	729
		Analysis of. (Mangold) (illus.)	860
		Composition of. (Buisine)	52
		Detection of Vegetable Wax in. (Rottger)	165
		Determination of Pine-Rosin in. (Rottger)	575
		Paraffin, Stearin, and Stearic Acid, Analysis of Mixture of.	
		(Jean)	728
		The Bleaching of. (Buisine)	52
		Beet Molasses, Analysis of the Calcined Vinasse from. (Heyer)	861
		Beetroot Molasses, Potassium Carbonate from Crude Residue	
		of. (Greif) (illus.)	136

Matters, Manufacture of Blue. (P) Kern and Sandoz	131	Constants Employed in the Analysis of Fats and Oils, On the Revision of. (Thomson and Ballantyne)	233
Matters, Manufacture of Blue. (P) Wilcox. From The Farb. vorm. Bayer and Co.	761	Consular Reports, Extracts from 169, 281, 392, 491, 580, 663, 806, 930, 1012	
Matters, Manufacture of New. (P) Durand and others	539	Conventions in Germany. (T.R.)	171
Matters, Manufacture of Nitrated. (P) Huray. From La Soc. Anon. des Matieres Colorantes de St. Denis	358	Conversione at Dublin	601
Matter, Manufacture of Soluble Blue. (P) Lake. From Ochler	132	Converter Bottoms, Refractory Linings for. (P) Versen	145
Matter of Red Carboxylic Acid. (Fahnestock)	153	Cooling Vessel for Foods. (P) Homer and Hazel	1020
Matters of the Anthraquinone Series. (Schmidt)	596	Copper, Action of, on Resistance of Colours to Light. (Scheurer)	460
Matters of the Induline Class, Production of Soluble Blue. (P) Huray. From La Soc. Anon. des Matieres Colorantes and Dr. Chapuis	132	And Aluminium Alloys of. (Regelsberger)	1034
Matters of the Induline Series Soluble in Water. (P) Huray. From The Farb. vorm. Meister, Lucius, and Brunnig	132	And Cadmium, Separation of. (Wells)	1038
Matters, Preparation of, with Gamma-amido-naphthol-sulphonic Acid. (P) Pitt. From Cassella and Co.	917	Canadian Customs Decisions Respecting. (T.R.)	279
Matters, Production of. (P) Hall	159	Childan Exports of. (T.R.)	75
Matters, Production of. (P) Huray. From The Soc. of Chem. Industry, Basle	439	Depositing Process, the Elmore. (Engineering)	262
Matter, Production of a Yellow. (P) Huray. From The Farb. vorm. Meister, Lucius, and Brunnig	439	Deposits of Sulphur Canada. (Bell)	372
Matter, Production of a Yellow. (P) Geigy	762	Glance, Oxidation of, by Electricity. (Smith and Wallace)	1037
Matters, Production of Azo. (P) Wilcox. From The Farb. vorm. Bayer and Co.	760	Holpner's Process for Obtaining, Direct from its Ore	469
Matters, Production of Black. (P) Huray. From The Soc. of Chem. Industry in Basle	761	Injurious Action of, on Rubber. (Dewar)	71
Matters, Production of Black, from Amidolavopurpurine and Amido-antra-purpurine. (P) Huray. From The Farb. vorm. Meister, Lucius, and Brunnig	219	Manufacture of. (P) Twyman	260
Matters, Production of Blue. (P) Dawson	916	Manufacture of. (P) Vivian	551
Matters, Production of Brown. (P) Shulite. From Geigy and Co.	218	Mattes and Ores, Treating Thimblefoss. (P) James	1012
Matters, Production of, from Substituted Benzidines. (P) Dawson and Hirsch	760	Method of Hunt, Douglas and Hauch for Extracting. (Stahl)	468
Matter, Production of Grey. (P) Huray. From The Farb. vorm. Meister, Lucius, and Brunnig	219	Ores, Furnaces for Smelting. (P) Richards	1010
Matter, Production of Grey Basic. (P) Huray. From The Farb. vorm. Meister, Lucius, and Brunnig	219	Physical Properties of Some Alloys of	762
Matters, Production of New Basic Blue. (P) Pitt. From Cassella and Co.	558	Production of Refined. (P) James	1012
Matter, Production of Substantive. (P) Johnson. From The Badische Anilin und Soda Fabrik	219	Refining. (P) Bell	935
Matter, Production of Yellow. (P) Shulite. From Geigy and Co.	132	Slates, Treatment of, at Mansfield. (Egleston)	702
Matter, Production of Yellow Basic. (P) Huray. From The Soc. of Chem. Industry, Basle	132	Smelting Furnaces, Fitting Refuse of. (P) Bath	1011
Matter, Sulpho-Acids of a Red Basic Naphthalene. (P) Johnson. From The Badische Anilin und Soda Fabrik	539	Smelting, the Basic Process applied to. (Gilchrist)	4
Colours, Action of Acids on Dyed. (Hummel)	833	Tempering, at Castings of. (P) Eyraud	19
Action of Copper on Resistance of, to Light. (Scheurer)	900	Use of Liquid Fuel in Smelting. (Schmiedel)	1008
Action of Milling on. (Hummel)	833	Cops, Apparatus for Dyeing and Treating. (P) Wise. From Monner and Co.	156
Action of Securing on. (Hummel)	833	Corda Cylinders	250
Action of Stoving on Dyed. (Hummel)	833	Corandrol. (Semmler)	383
Apparatus for Printing in. (P) Thompson. From Auguste Godchaux	766	Corn Product for Brewers' Use. (P) Bates, jun.	154
Fastness of Dyed, to Light and Air. (Woscher)	634	Products, Manufacture of. (P) Hindustan	266
		Products, Manufacture of New. (P) Thompson. From Lankoll	266
		Cork, Bleaching Ground. (P) Walton	779

Lards, Quality of Various. (Engler and Rupp).....	801
Laurium Mines in 1890, The. (F.R.).....	393
Laurotetamine. (Greshoff).....	290
Lavender, its Cultivation and Distillation. (Sawyer) (illus.).....	478
Lavoisier Medal, Award of the. (F.R.).....	581
Lead and Sodium Alloys of. (Greene and Wahl).....	112
And Zinc, Corrosion of, in Contact with Cement. (Seger).....	140
And Zinc, Obtaining White Compounds of, for Making Pigments. (P) French.....	1015
Apparatus for Desilverising. (P) Edwards. From Honold. (illus.).....	1012
Blast Furnace, Coal in the. (Dwight).....	933
Chambers for Manufacture of Sulphuric Acid. (P) Walter and Böng.....	1007
Chromates, the Chemistry of. (Weber).....	710
Coating Metals with. (P) Makon.....	157
Converting Carbonate of, into Basic Salt. (P) Zentler.....	557
Determination of, as an Analogue. (Vortmann).....	1036
Estimation of Sulphur in. (Hampe).....	486
Fibre, Apparatus for Manufacture of. (P) Torkington. From Morris.....	776
Fluxes for Coating Metals with. (P) Clark. From Horgan.....	704
Manufacture of Carbonate of. (P) Morris.....	714
Manufacture of Red. (P) Larrow.....	574
Manufacture of White Pigments from Sulphate of. (P) Wood.....	149
Process for Manufacture of White. (P) Bischof.....	811
The Chemical Changes between Nitric Acid and. (Veley).....	208
Pipe, Action of Water on. (Waller).....	815
Pipes, The Destruction of. (Hartmann).....	693
Sulphate, Manufacture of. (P) Pennington.....	1016
Wire, Electrodes of. (P) Legay.....	706
Wire, Manufacture of. (P) Legay.....	706
Lens for Annealing Sheets of Glass. (P) Chance.....	518
Leather. (Class XIV)..... 55, 151, 290, 375, 472, 557, 648, 714, 780, 811, 938, 1017	
Apparatus for Treating. (P) Hunting.....	780
Cloth, Manufacture of. (P) Frampton.....	151
Dyeing, Application of Alizarine in. (Koeschlin and Kuecht).....	230
Elephant.....	558
Finishing Machine. (P) Horn. From Lemmer.....	375
Machinery for Working. (P) Wilson.....	618
Machines for Colouring. (P) Skueck and Jelen.....	649
Preparing Elastic Caoutchouc-like. (P) Kuhne.....	618
Recovery of Esson from Waste. (P) Grimshaw.....	151
Shrinking, by Means of Fat. (P) de Hessele.....	1017
Substitute for. (P) Drew.....	619
Treatment of, for Dyeing Purposes. (Shaw).....	219
Waste, Utilising. (P) Barton.....	558
Waterproofing. (P) Lawrence.....	558
Leblanc Process, The Present State of the. (F.R.).....	583
Levithum, Preparation of, from Plant Seeds. (Schulze and Likieruk).....	381

Manganese and Zinc, Quantitative Separation of, (Jannasch and Metzger)	659
Bronze Colour, Formation of, (Depierre)	561
Bronze Colour, Formation of, (Frey)	561
Decomposing Nitrates of, (P) Wischm	254
Determination of, in its Ores and Alloys, (Pattinson)	338
New Volumetric Method of Estimating, (Blum)	703
Ores, Production of, in the United States, (T.R.)	582
Precipitation of, as Ammonium Manganous Phosphate, (McKenna)	387
Physical Properties of some Alloys of, (Frey)	702
Quantitative Separation of, from Nickel, Cobalt, and Mixtures thereof, (Jannasch and Franzek)	1037
Sulphide as a Pigment, (de Clermont and Guio)	712
Vaporising Solutions Containing Nitrates of, (P) Wischm	254
Mangel-Wurzel, Experiments with, at Rothamsted	939
Manilla Paper, Manufacture of, (P) Atherton, From Beek	268
Manno-Saccharic Acid, on <i>d</i> - and <i>l</i> - (Fischer)	559
Manure, Ammonium Phosphate as a, (Vogel)	1017
And Sludge, Drying, (P) Hasina and Cornish	26
Apparatus for obtaining from Waste Animal Substances, (P) Lake, From de la Croix	649
Industry, The Position of the Artificial	841
Making Superphosphate, (P) Jelinek	649
Manufacture of Artificial, from Residues of Paper Making, (P) Pearman	939
Trade, Uniform Customs in the, (T.R.)	281
Works, Noxious Vapours of, (Morrison)	338
Manures, (Class XV) 156, 151, 261, 375, 558, 649, 711, 789, 841, 938, 1017	
Adulteration Bill, Artificial, (T.R.)	172
Nitrogenous Substances in the Manufacture of, (P) Fewson	264
Progress in Manufacture of Artificial, (Chem. Ind.)	151
Marble, Artificial, (P) Bruck	644
Imitation, (Marud)	771
Marbling Machine for Paper, Ac, (P) Bellamy	924
Margarine, Detection of, in Butter, (Leder)	728
The Netherlands Trade in, (T.R.)	733
Mash and Wort, Fermenting, (P) Funk	719
Match Industry, Development of the Russian, (T.R.)	394
Manufacture of Germany, The, (Kolbe and Co.)	171
Matches, (Class XXIV) 100, 100, 270, 384, 181, 373, 657, 793, 854, 917, 1028	
Improved Lucifer, (P) Rosen Rötter	571
Improvements in Lucifer, (P) Thompson, From Hess	161
Manufacture of, (P) Bell	571
Manufacture of Lucifer and other, (P) Sordet	855
Ventris, (P)	794
Mauritius, Customs Tariff of, (T.R.)	279
Meadow Land, Experiments on, at Rothamsted	938
Measures, Grease-Spot Photometer, (Vance)	18
Meat and Fish, Method for Preserving, (P) Grognet	175
Extracts, Action of, on Certain Metals, (Ballan)	379
Preparing Soluble Peptonised, (P) Etienne and Delhaye	719
Preservation of, (P) Falmagne	1021
Process and Apparatus for Preserving, (Dosiand and Roze)	177
Treating, Preserving and Packing, (P) Eardley, Cochrane and Wedd	61
Medical Extracts, Manufacture of, (P) Newton, From The American Embellishment Co.	792
Medicinal Compounds from Etheral Oils, (P) Johnson, From von Heyden (Nachfolger)	1027
Medium for Use with Chemical and Earth Colours, (P) Schmalz	159
Melting, Proceedings of the Tenth Annual	597
Melodinus laevigatus Bl., Alkaloid from, (Greshoff)	269
Melting Points, Apparatus for Determining, (Ebert)	574
Members Elected, Lists of, 2, 88, 184, 294, 496, 510, 526, 820, 882, 974	
Membranes, Treating Vegetable, to obtain Glutinous Substances, (P) Steiger and others	561
Menthyl, (Brühl)	1025
Menthylethylether, (Brühl)	1025
Merchaud Marks Act in France, The, (T.R.)	580
Mercurial Pumps, (P) Thompson, From Raps	240
Mercuric Chloride, Compounds of, (André)	724
Mercury Ammonium Chlorides, Preparation and Reactions of, (André)	638
Detection of, in Poisoning Cases, (Lecon)	659
Determination of, by Electrolysis, (Smith)	708
Export of, from Russia, (T.R.)	281
Pump, Automatic, (Stahl)	387
Vacuum Pumps, (P) Boly (illus.)	1032
Measure and Nona's Pyrometer, Application of, in Earthenware Trade, (Hecht)	138
Metal-bearing Substances, Centrifugal Apparatus for Treating, (P) Peck	775
Metal, Cement for, (Spence)	774
Centrifugal Apparatus for Treating and Renewing Molten, (P) Peck	574
Centrifugal Apparatus for Treating Molten, (P) Peck	572
Electro-Magnetic Separators for Separating from Slag, (P) Asklewin and Wilson	706
Galvanising Sheet, (P) Davies and Bayless	523

Plant, Apparatus and Machinery (Class I.)	34, 121, 238, 349, 418, 528, 624, 687, 749, 821, 906, 985
Fibres, Action of Nitric Acid upon. (Cross and Bevan)	89
Plants, Absorption of Ammoniacal Nitrogen by. (Griffiths)	101
Estimation of the Penta Glucos in. (de Chalmot and Tollens)	577
Quantitative Estimation of Pentoses in. (Stone)	1039
Plastering Compositions, Improvements in. (P) Robinson and Terry	141
Plastic Compounds for Building Purposes. (P) Vasson and La Soc. dite "La Suberine"	771
Material, Apparatus for Cutting and Delivering. (P) Anderson	161
Moulding Material, Production of. (P) Sochaczewski	549
Plates for Batteries. See Batteries.	
Plates, Apparatus for Development of Photographic, without Dark Room. (Watt) (illus.)	16
For Colour Printing, Production of. (P) Michaud	835
For Oil Presses. (P) Leechman (illus.)	708
For Straining Paper Pulp. (P) Watson	944
Wood-Wool Absorption. (Cameron)	164
Platinum and Some of its Alloys. (Heraeus)	773
Carbonoxide, The Compounds of. (Mylus and Forster)	955
Prints, Washing. (Huszar)	574
Speculation, The. (T.R.)	664
Plush, Compositions for Renovating the Colours of. (P) Thompson. From Mantner	923
Pneumatic Maltng Drums. (P) Johnson. From The Berliner Actiengesellschaft vorm. Freund and Co.	940
Polarisation in Electric Batteries, Means for Preventing. (P) Badcock and others	116
Polei, Principal Constituent of Oil of. (Pleissner)	180
Polish, Furniture. (P) McMillan	375
Porcelain, Blue Sub-Glaze Colour for. (Lauth)	769
Cracked. (Lauth and Dutilleul)	769
New Process of Firing, at Limoges. (T.R.)	170
Production of High-Temperature Blue on. (Lauth)	159
Soldering	869
Tablets or Letters, Manufacture of. (P) Robson	567
Portland Cement. (Ding. Polyt. J.)	927
Portugal, Antimony Mining in. (Vogel)	837
Postage, Reduction of, on Books, Patterns, &c. (T.R.)	1043
Potash and its Derivatives: Review for 1890. (T.R.)	282
Electrolytic Production of Caustic. (P) Richardson and Holland	699
From Waste Potassium Salts. (P) Wise. From The Chem. Fab. Buckau	707
Manufacture of. (P) Eilershausen	546
Manufacture of Soda and. (P) Eilershausen	543
Production of, from Potassium and Magnesium Carbonate. (P) Precht	255
Rendering Permanganate of Potous. (P) Parkinson	947
Salts Industry of Stassfurt in 1889. (T.R.)	582
Potassium and Magnesium, Purifying Double Carbonate of. (P) Precht	547
Bitartrate, Solubility of. (Blarez)	188
Carbonate, Manufacture of, from Crude Residue of Beetroot Molasses. (Greiff) (illus.)	136
Chloride from Crude Residue of Beetroot Molasses. (Greiff) (illus.)	136
Manufacture of. (P) Castner (illus.)	777
Persulphate. (Marshall)	1094
Salts, Effect of Haloid, on Solubility of Potassium Sulphate (Blarez)	698
Salts, Influence of Neutral, on Solubility of Potassium Bitartrate. (Blarez)	717
Salts, New Discovery of, in Germany. (T.R.)	665
Salts, Occurrence of Ammonium Chloride in Stassfurt. (Neimke)	826
Salts, Treatment of Impure Waste. (P) Wise. From The Chemische Fabrik Buckau	767
Separation of Sulphate or Chloride of. (P) Roth	270
Sulphate from Crude Residue of Beetroot Molasses. (Greiff) (illus.)	136
Potato, Growth of Improved Varieties of, for French Distilleries. (Girard)	378
Disease, Remedies for. (T.R.)	498
Potatoes, Experiments on, at Rothamsted	939
Pottery. (Class VIII.) 46, 138, 255, 367, 468, 548, 645, 699, 709, 926, 1007	643
Apparatus for drying. (P) Weigelm	255

Sulphuretted Hydrogen. See Hydrogen.		Tea, Preparation of Extract of. (P) Sonstadt.....	65
Sulphuric Acid, Action of, on Quinol. (Steinhil).....	854	Producing Infusions of, free from Tannin. (P) Grimshaw	155
Acid, Apparatus for Concentrating. (P) Webb.....	768	Teas, Investigation of China. (Dvorkovitz).....	276
Acid, Apparatus for Manufacture of. (P) Deplace (illus.)	274	Temperatures, Effects of Abnormally Low, on Constructional	
Acid Chambers. (P) Walter and Boenig.....	1007	Iron. (Steiner).....	1008
Acid, Detection of Free, in Plastered Wines. (Magnier de		Tempering Fluid for Treating Steel. (P) Tweedy.....	115
la Source).....	175	Terebenthene. (Varet).....	722
Acid from Waste Potassium Salts. (P) Wise. From The		Terne Metal, Apparatus for Coating Hoop Iron with. (P)	
Chem. Fab. Buckau.....	767	Johns.....	261
Acids, Furnaces for Concentrating. (P) Negrier (illus.) ..	16	Plates, Treatment of Scrap. (P) Carvz.....	570
Acid Manufacture: the Chamber Process. (Schertel).....	138	Terpene, A New. (Wallach).....	788
Acid, Method and Apparatus for Concentrating. (P)		From Compressed Gas Oils. (Etard and Lambert).....	688
Negrier.....	639	Terpenes and Allied Compounds, Studies of the. (Armstrong	
Acid, On Apparatus for Concentration of. (Herrens).....	160	and Pope).....	653
Acid, State of Combination of, in Plastered Wines. (Mag-		And Camphor. (Wallach).....	850
nier de la Source).....	175	And Ethereal Oils. (Wallach).....	789
Sulphurous Acid, Apparatus for Recovering. (P) Kellner.....	423	And Their Derivatives, The. (Brühl).....	1025
Acid or its Salts, Apparatus for Production of Solutions		Olefine. (Semmler).....	568
Containing. (P) Horsley and others.....	543	Terpinene. (Wallach).....	851
Chloride, Analysis of. (Le Roy).....	274	Terpinolene. (Wallach).....	851
Sulphurate of Calcium, Production of. (P) Leith.....	255	Tests for Hydraulic Cements, Hot. (Deval).....	255
Sunlight, Action of, on Organic Compounds. (Klinger and		Tetrahydro-orthimidazoquinadine. (Bamberger and Walz).....	999
Standke).....	630	Tetrahydroquinoline, Homologues of. (Bamberger and Walz)	999
Superphosphates, Apparatus for Disintegrating. (P) Askham		Tetra-methylidiamidobenzhydrol, Condensation of. (Nolting	
and Wilson.....	749	and Polnowsky).....	120
Switzerland, Classification of Articles in Customs Tariff of.		Tetranitrodiphenyl- <i>o</i> -disulphonic Acid. (Lamprecht).....	601
(T.R.).....	663, 732, 805, 957	Tetrazo Dyes, On the. (Werner).....	916
Customs Decisions in. (T.R.).....	168	Tetrazodiphenyl- <i>o</i> -disulphonic Acid. (Lamprecht).....	600
Syracuse, Works for Automatic Supply of Brine at. (Brush).....	162	Texas, Further Discoveries of Tin in. (T.R.).....	171
Syrup, Improving the Flavour of. (P) Duncan.....	781	Textile Factories, Apparatus for Cleansing. (P) Hutchinson.....	924
Syrups, Apparatus for Manufacturing Cold, of Determined		Factories, Apparatus for Dyeing. (P) Corron.....	44
Density. (P) Klein and Dethm.....	843	Factories, Apparatus for Finishing. (P) Douglas.....	133
Sylvestrene. (Wallach).....	851	Factories, Bleaching Linen, Cotton, and other. (P) Webb.....	923
Sz-Chuen, Opium Cultivation in. (T.R.).....	74	Factories, Calendering. (P) Hadow.....	359
		Factories Dyed with Indigo, Obtaining Designs in Red on.	
		(P) Ethers.....	924
		Factories in France, The Conditioning of. (T.R.).....	495
		Factories, Machinery Connected with the Bleaching of. (P)	
		Reid and Edmiston.....	697
		Factories, Removing Fatty Matters from. (P) Hutchinson.....	918
		Factories, Rendering Waterproof by One Treatment. (P)	
		Miller.....	957
		Fibres, Bleaching. (P) Hitchcock-Spencer.....	541
		Fibres, Dyeing. (P) Holliday.....	765
		Fibres, Dyeing and Treating. (P) Wise. From Mummer	
		and Co.....	136
		Fibres, Retting and Scouring. (P) de la Roche.....	539
		Materials, Apparatus for Dyeing and Treating. (P) Sut-	
		cliffe.....	696
		Materials, Apparatus for Preparation of. (P) Feiler.....	133
		Plants, Machines for Decorticating. (P) Favier.....	540
		Textiles, Compositions for Preservation of. (P) Truman.....	133
		Cotton, Wool, Silk, &c. (Class V.)..... 80, 133, 249, 339, 539, 634,	
		762, 834, 918	
		Dyeing, in Hyposulphite Vat. (P) Abel. From Rotten.....	835
		Rendering, Waterproof and Non-combustible. (P) Baswitz	133
		Theobroma, of Trinidad.....	250
		Thermo-Chemical Study on the Reduction of Metals from their	
		Ores (Hartley).....	466
		-Electric Batteries. (P) Gouraud.....	834
		Thermometer, Air. (Sabine) (illus.).....	162
		Thermometers or Pyrometers. (P) Murrie.....	625
		Thiocarbamide, Addition Compounds of. (Emerson Reynolds)	571
		Thiocarbamides, Reversal of the Negative Photographic Image	
		by. (Waterhouse).....	66
		Thionines, Manufacture of Sulphonated. (P) Cassella and Co.	337
		Production of Sulphonated and Dye-stuffs therefrom. (P)	
		Pitt. From Cassella and Co.....	917

T

Tachydrate, Synthesis of. (de Schultze).....	364
Tallow Trade of Russia, The. (T.R.).....	394
Tan, Furnaces for Burning. (P) Brown.....	230
Tanneries, Treating Waste from. (P) Calvert and Chasler.....	36
Tannic and Gallic Acids, Italian Customs Report on.....	55
Tannin Analysis, Note on Löwenthal's Method of. (Whitley	
and Wool).....	523
Matters of Agarobilla and Myrabolams. (Zoffel).....	831
Producing Infusions of Tea Free from. (P) Grimshaw.....	155
Recovery of, from Waste Leather. (P) Grimshaw.....	151
Substitutes for. (P) Thurn.....	714
Tanning by Aid of Electricity. (Rideal and Trotter).....	425
Improvements in. (P) Pujos.....	472
Leather, Glue, and Size. (Class XIV.)..... 55, 151, 290, 375, 472,	
557, 648, 714, 780, 841, 938, 1017	
Materials, The Oxidation of. (Jahoda).....	172
Product in Angola, New. (T.R.).....	281
Woods. (Armandon).....	55
Tannins, Estimation of, in Acid Liquors. (Bardel).....	803
Source of Error in Gravimetric Estimation of. (Koch).....	803
Tar, Continuous Distillation of. (P) Prople (illus.).....	455
Distillation of Coal. (Windmann).....	912
Distilling. (P) Folan.....	154
Oils Soluble in Water, Rendering. (P) Dammann.....	350
Paraffin and Bitumen in Brown-Coal. (von Boyen).....	451, 689
Phenol of Birchwood. (Frenger).....	354
Products, &c. (Class III.)..... 38, 129, 246, 354, 458, 534, 629, 688,	
753, 825, 919, 986

W

Wall Paper, Substitute for. (P) Baker. From Silver and Ritchie.....	259
Walls, Material for Decorating. (P) Palmer.....	1022
Water, Action of Galvanised Iron on Drinking. (Haines).....	155
Action of, on Lead Pipe. (Waller).....	845
Action of Running, on Certain Minerals. (Thoulet).....	739
Alteration of Density of, on Heating. (Mendeleeff).....	739
Analysis, Ammonia Process of. (Haines).....	1037
Analysis, Local Standards in. (Haines).....	913
Apparatus for Distilling. (P) Normandy.....	908
Apparatus for Distilling Sea-. (P) Gilmour.....	625
Apparatus for Evaporating Salt-. (P) Kerr.....	419
Apparatus for Filtering. (P) Baker.....	625
Apparatus for Producing Fresh, from Salt. (P) Hocking.....	822
Apparatus for Purification of. (P) Devaux.....	379
Apparatus for Softening and Purifying. (P) Brewinlow.....	128
Bleaching Cotton by Means of Oxygenated. (Prud'homme).....	851
Containing Magnesium Chloride, Boiler Feed-. (Goldberg).....	418
Determination of Albuminoid Nitrogen in. (Wagner).....	487
Estimating Organic Matter in. (Young).....	883
Estimating the Oxygen Dissolved in. (Lüssier).....	726
Estimation of Dissolved Carbon Dioxide in. (Leeds).....	726
Estimation of Dissolved Oxygen in. (Kisch).....	486
Filters for Purification of. (P) Smith.....	127
Improvement of Inferior, by Sand Filtration. (Schultze).....	177
Manufacture of Ozone. (P) Dietrich.....	725
Neutrality of. (Mylius and Foerster).....	853
Notes on Analysis of Effluent. (Thomson).....	339
Preparation of Material for Treatment of Impure. (P) Candy.....	156
Process and Apparatus for Purifying. (P) Devonshire.....	127
Process and Apparatus for Softening. (P) Lawrence (illus.).....	624
Purification of. (Zabrowski).....	238
Purification of, by Distillation. (P) Young.....	128
Purification of, by Metallic Iron. (Devonshire).....	912
Solvent Action of, upon Glass. (Mount, Scient.).....	464
Source of Error in Determination of Nitrates in. (Bartram).....	951
Sterilising. (P) Rouart.....	846
The Filtration of, through Calcined Infusorial Earth. (Nordmeyer).....	729
The Solubility of Gases in. (Winkler).....	387
The Treatment of Hard. (Archbutt and Dealey) (illus.).....	511
Use of Galvanised Iron Pipes for Conveying. (Haines).....	912
Utilisation of Chalybeate Springs for. (Pierke).....	722
Volatile Organic Matter in Potable. (Young).....	883
-Gas, Application of, to Manufacture of Iron and Steel. (P) Fox.....	552
-Gas, Comparative Experiments on Boiling with Coal-Gas and. (Coghevin).....	108
-Gas Furnaces. (P) Deighton.....	259
-Gas, Manufacture of. (P) Fox and Glass.....	687
Water-Gas. See Gas.	
Waterproof Garments, Manufacture of. (P) Frankenburz.....	1046
Waterproofing Composition. (P) Chapman. From The United Indurated Fibre Co.....	1047
Composition. (P) Dysko.....	151
Textiles. (P) Basswitz.....	133
Waters, Fluorides as Agents for Softening. (Doremus).....	155
Manufacture of Aerated or Mineral. (P) Saunders.....	651
Rapid Method of Estimating Nitrates in Potable. (Harrow).....	727
Reasons for Abandoning Clark's Method for Estimating Hardness in. (Leeds).....	727
Sulphocarbazole as a Reagent for Distilled. (Viron).....	809
"Wash Greys," Preparation of. (Behrens and Watson).....	924
Washing Jelly. (P) Waddell.....	1045
Waste from Distilleries, Starch Works, &c., Utilising, for Preparation of Fuel. (P) Parks.....	844
Wastes, Treating Heated Liquid. (P) Nelson.....	626
Wax, Composition and Bleaching of Bees-. (Buisine).....	52
Composition of White. (Buisine).....	52
Detection of Vegetable-wax in Bees-. (Roltger).....	105
On Hubl's Method for the Examination of. (Benedikt and Mangold).....	869
Production of China.....	555
Waxes, Analysis of Russian. (Antonshovich).....	1014
Weather-Proof Coatings for Buildings. (Koller).....	932
Weights and Measures, Use of Metric, in Export Trade. (T.R.).....	360
Welding, Practical Aspects of Electric. (Perrine).....	795
Weldon Plant, Utilising, for Manufacture of Precipitated Phosphates. (P) de Wilde.....	836
Wells, Necessity for Systematic Inspection of, in Towns. (Woodman).....	721
Use of Galvanised Iron for Artesian. (Haines).....	155
Weselsky's Resorcinol Blue, Synthesis of. (Nietzki).....	1002
Whalebone, Imitation. (P) Knight.....	261
Wheat, Experiments with, at Rothamsted.....	398
Whisky, Manufacture of. (P) Taylor.....	562
The Chemistry of. (Allen).....	395, 519

PAGE

White Lead, Manufacture of. (P) Gardner.....	713
Lead, Manufacture of. (P) Lake. From Bahl.....	1046
Lead, Process for Manufacture of. (P) Bischof.....	841
Pigment. (P) Grimshaw.....	264
Wine, Addition of Sugar and Water to Acid. (Author).....	551
Apparatus for Aeration of. (P) Sharp.....	295
Detection of Sugared, in Natural White Wine. (Socha-czewski).....	782
Fermenting Process for. (P) Salomon.....	378
Method of Improving. (P) Battalle.....	562
Rapid Method of Estimation of Common Salt in. (Gon-doin).....	863
Salts of Strontium in. (T.R.).....	1043
The Properties of Fig-. (Carles).....	718
The Use of Saccharine in.....	843
Lees, Analysis of Crude Tartar and. (Phillips and Co.).....	167
Lees, Determination of Acid Tartrate in. (Bailh).....	862
Wines. (Class XVII.).....	57, 154, 265, 378, 471, 561, 651, 717, 782, 845, 990, 1049
And Spirits, Improvements in. (P) Snelling.....	1049
Detection of Free Sulphuric Acid in Plastered. (Magnier de la Source).....	475
Detection of Sugared Wine in Natural Wine. (Socha-czewski).....	782
Improvements in. (P) Simpson and Cox.....	651
Influence of, on Pepsic Digestion. (Huzouenq).....	782
Maturing. (P) Budden.....	843
On Italian. (Niederhauser).....	475
Production of Sparkling. (P) Bruns.....	1049
State of Combination of Sulphuric Acid in Plastered. (Magnier de la Source).....	475
Wire, Compound Gold. (P) Burdon.....	145
Electro-Plating. (P) Henning.....	706
Wolfram Mining in New Zealand.....	559
Wood, Composition of. (Hbl).....	563
Impregnation of. (P) Oucken.....	771
Influence of Alkalis, &c., on. (Hbl).....	563
Lepidine, a Reagent for. (Hbl).....	465
Preparing, for Manufacture of Wood Fibre. (P) Kellner.....	1022
Preservation of, Imbedded in the Earth. (P) Ches-brough.....	780
Pulp, Determination of Mechanical, in Paper. (Benedikt and Bamberser) (illus.).....	576
Pulp, Economising Heat in Apparatus for Boiling. (P) Thorth.....	157
Pulp, Estimation of Mechanical, in Paper. (Herzberg).....	664
Pulp, Purifying. (P) Joel and Ryan.....	566
Pulp, Soda-. (Hennefeld).....	786
Pulp Trade of America, The. (T.R.).....	74
Spirit, Recovery of, in Manufacture of Charcoal. (P) Zwillingner.....	129
Sugar and Wood Gum. (Allen and Tollens).....	173
Wood Absorption Plates. (Camerer).....	161
Woods, Tanning. (Armandon).....	55
Wool. (Class V.).....	132, 249, 359, 539, 631, 762, 831, 918
Apparatus for Testing. (P) Jaegermayer and Michel.....	634
Carbonising of, in Presence of Silk. (Koechl).....	230
Cleansing. (P) George.....	918
Dyeing, Application of Chromium Fluoride in.....	763
Dyeing, Colouring Matters for. (P) Imray. From The Farb. vorn. Meister, Lucius, and Bruning.....	633
Dyeing or Printing. (P) Holliday.....	135
Fibres, Treating. (P) Smith.....	131
Mordanting and Dyeing. (P) Smith.....	923
Permanent and Fugitive Colours to Light on. (Ernsner).....	865
Process and Apparatus for Dyeing. (P) Cavailles.....	636
Treating, Preparatory to Spinning. (P) Pilard.....	133
Washing and Scouring. (P) Arnott and others.....	134
Fat, Manufacture of Saponifiable Fatty Matter from. (P) Roos.....	709
Grease, Production of Odourless. (P) Feuerlein and Lohsen.....	709
Wort and Beer, Bacteria Occurring in. (Zeidler).....	154
Mixing or Blending. (P) Littleton.....	295
Preparation of. (P) Rach.....	940

X

Xylan and Xylose. (Allen and Tollens).....	475
Xylene, Ethylbenzene in Commercial. (Noelting and Palmer).....	912
Xylidine, Ortho 1:2:3. (Mouton).....	830
Xyloic Acid. (Allen and Tollens).....	475
Xylonite, Application of. (P) Anders and Elliot.....	380
Xylose, Derivatives of. (Bertrand).....	716
From Maize Cobs. (Stone and Lotz).....	359
On. (Fischer and Stahel).....	559

Yarn, Apparatus for Dyeing. (P) Peck	45
Apparatus for Dyeing and Bleaching. (P) Thompson	15
From Kornfeld	627
Machinery for Dyeing Hanks of. (P) Wardle	765
Machines for Bleaching and Treating. (P) Spencer (illus.)	521
Yarns, Apparatus for Scouring and Dyeing. (P) Laillaw (illus.)	523
Bleaching Linen and Cotton. (P) Webb	548
Production of Dyed Cotton. (P) Salzmann	782
Yeast, Analysis of Tye, by Hansen's Method. (Jorgensen)	378
Apparatus for Production of. (P) Lake, From Jorgensen and Bergh	561
Appliance for Aerating. (P) Maynard	940
Manufacture of. (P) Lake, From Brunn	265
Manufacture of German or Dried. (P) Fordred	561
Preparation of. (P) Soc. Gen. de Maltose	1049
Production of Dry. (P) Genze and Sigmund	1049
Purification of. (P) Elton	843
Receivers. (P) Lecker and Howell	265
Recovery and Utilisation of. (P) Campbell	266
Treatment of, for Bread-making. (P) Leconte	
Yellow Basic Colouring Matter. (P) Inray, From The Soc. of Chem. Industry in Basle	132
Colouring Matter. (P) Inray, From The Farb. vorm. Meister Lucius and Bruning	459
Colouring Matter, Production of. (P) Gengy	762
Dyes or Colouring Matter. (P) Shillito, From Gengy and Co.	132
Yorkshire Section Inaugural Dinner	903

Zinc and Lead, Corrosion of, in Contact with Cement. (Sezer)	140
And Lead, Obtaining White Compounds of. (P) French	1015
And Manganese, Quantitative Separation of. (Jannasch and McGregor)	659
-Blonde Fume, Utilising. (Krause)	934
Chromates. (Weber)	711
Desilverisation. (Roessler and Edelmann)	550
Desilverisation by Means of. (Roessler and Edelmann)	552
Determination of, as an Amalgam. (Vortmann)	5036
Diluent Solubility of Chemically Pure, in Acids. (Weeren)	955
Errors in Volumetric Determination of, by Potassium Ferrocyanide. (Moldenhauer)	574
For Galvanic Batteries. (P) Moseley	554
From Fine Dust of Zinc Furnaces. (Jensch)	112
Obtaining by Electrolysis. (P) Elmore	146
Obtaining Metallic, by Electrical Decomposition. (P) Edwards, From Lange	647
Ores, Apparatus for Reduction of. (P) Lunningh	145
Production of, from Ores, &c. (P) James	935
Production of, from Oxidised Ores. (P) Parker and Robinson	776
Recovery of, from Galvanised Iron and Steel. (P) Grimshaw	144
Statistics of Germany. (T.R.)	959
Zirconia as a Substitute for Lime in the Oxyhydrogen Light. (Kochs)	37

ERRATUM.

This Journal, page 849, col. 2, for "*Catechol*" throughout read "*Catechin*."

INDEX OF NEW BOOKS.

	PAGE		PAGE
Aids in Practical Geology. Grenville A. J. Cole.....	71	Law and Practice Relating to Letters Patent for Inventions. Treatise on the. R. Frost.....	864
Alkali Makers' Handbook, The. G. Lunge and F. Harter....	956	Mensuration and Gauging, The Pocket-Book of. J. B. Mant..	579
Theoretical and Practical Treatise on the Manufacture of. G. Lunge.....	865	Metallurgy, An Introduction to the Study of. W. C. Roberts-Austen.....	72
Analysis and Valuation of Solid, Liquid, and Gaseous Fuels. H. Joshua Phillips.....	71	Of Steel, The. H. M. Howe.....	279
Fresenius' Quantitative, Vol. II. Translated by C. E. Groves.....	279	Odours of Plants, Methods of Obtaining the. Piesse.....	865
Quantitative Chemical. F. Clowes and B. Coleman.....	957	Organic Analysis of Potable Matters, The. J. A. Blair.....	957
Bulgaria, The Rose Industry of. Christoff.....	865	Chemistry, A Handbook of Industrial. S. P. Sadtler.....	956
Chemiker-Kalender, 1892. Von R. Biedermann.....	956	Organischen Chemie, Lehrbuch der. V. Meyer and P. Jacobson.....	168
Chemistry, A Dictionary of Applied. T. E. Thorpe, Vol. II....	489	Perfumery, Piesse's Art of. C. H. Piesse.....	865
Of Illuminating Gas, The. Norton H. Humphrys.....	662	Pocket-Book of Mensuration and Gauging. J. B. Mant.....	579
In Space. J. E. Marsh.....	391	Prüfung der Chemischen Reagentien auf Reinheit. C. Krauch.....	490
Chemisch-Technisches Repertorium. Dr. Emil Jacobsen.....	468	Quantitative Analysis, Fresenius', Vol. II. Translated by C. E. Groves.....	279
Chemische Technologie der Gespinnstfasern. O. N. Witt.....	1041	Chemical Analysis. F. Clowes and B. Coleman.....	957
Coal, and what We Get from it. A Romance of Applied Science. Raphael Meldola.....	489	Resins, Varnishes and Fossil. R. Ingham Clark.....	662
Colour Measurement and Mixture. Capt. W. de W. Abney....	490	Rose Industry of Bulgaria, The. Christoff.....	865
Dictionary of Applied Chemistry. T. E. Thorpe. Vol. II....	489	Schrbuch der Organischen Chemie. V. Meyer and P. Jacobson.....	168
Encyclopedie English-German and German-English. Part I, English-German. Dr. E. Muret.....	279, 662	Solutions. W. Ostwald. Translated by M. M. Pattison Muir.	864
Elementary Lessons in Heat, Light, and Sound. D. E. Jones.	490	Solutions Sucrees, Titrage des, par la Determination de leurs Densites a la Temperature de 15° Centigrade. C. Scheibler.....	866
Encyclopedic English-German and German-English Dictionary. Part I, English-German. Dr. E. Muret.....	279, 662	Steel, The Metallurgy of. H. M. Howe.....	279
Fortschritte der Theerfarbenfabrikation und Verwandter Industriezweige. P. Friedländer.....	864	Sulphuric Acid and Alkali, Theoretical and Practical Treatise on the Manufacture of. G. Lunge.....	865
Fresenius' Quantitative Analysis, Vol. II. Translated by C. E. Groves.....	279	Synthetischen Darstellungsmethoden der Kohlenstoff-Verbindungen. Karl Elbs.....	489
Fuels, Solid, Liquid, and Gaseous, Their Analysis and Valuation. H. Joshua Phillips.....	71	Tabellarische Uebersicht der Kunstlichen Organischen Farbstoffe. Von Gustav Schultz and Paul Julius.....	662
Gas, The Chemistry of Illuminating. Norton H. Humphrys....	662	Technisch-Chemisches Jahrbuch, 1889-90. Dr. R. Biedermann.....	72
Gauging and Mensuration, The Pocket-Book of. J. B. Mant..	579	Titrage des Solutions Sucrees, par la Determination de Leurs Densites, a la Temperature de 15° Centigrade. C. Scheibler.....	866
Geology, Aids in Practical. Grenville A. J. Cole.....	71	Varnishes and Fossil Resins, Notes on. R. Ingham Clark....	662
Handbook of Industrial Organic Chemistry. S. P. Sadtler....	956	Water Analysis. 8th Edition. J. A. Wanklyn and E. T. Chapman.....	579
Heat, Light, and Sound, Elementary Lessons in. D. E. Jones.	490	Examination of, for Sanitary and Technical Purposes. H. Lefmann and W. Beam.....	864
Introduction to the Study of Metallurgy. W. C. Roberts-Austen.....	72	Waters, The Organic Analysis of Potable. J. A. Blair.....	957
Inventions, Treatise on the Law and Practice Relating to Letters Patent for. R. Frost.....	864	Wattles and Wattle Barks. J. H. Maiden.....	866
Kohlenstoff-Verbindungen, Synthetischen Darstellungsmethoden der. Karl Elbs.....	489		

● EYRE and SPOTTISWOODE,
East Harding Street, London, E.C.

LIST OF MEMBERS.

A

Abbott, John, Braemar House, Lancaster Gate, Hyde Park, W.
 Abel, Sir F. A., 40, Cadogan Place, London, S.W.
 Abraham, A. C., Stanley Rock, St. George's Mount, New Brighton (Journals); and 87, Bold Street, Liverpool.
 Acland, Sir H. W., Bart., Radcliffe Library, Oxford.
 Adam, A. Learmouth, 40, Sir Michael Street, Greenock, N.B.
 Adam, J. B., 172, Leith Walk, Edinburgh.
 Adams, M. A., Ashford Road, Maidstone, Kent.
 Adams, J. W., 74, Oxford Street, Regent Road, Salford, Manchester.
 Adamson, G. P., Easton, Pa., U.S.A.
 Addie, J., Langloan Ironworks, Coathbridge, N.B.
 Adkins, H., Ley Hill, Northfield, near Birmingham.
 Adriaance, John S., c/o Banning, Bissell, & Co., Huntingdon, Pa., U.S.A.
 Affleck, Dr. J., Mill House, Woolton, near Liverpool.
 Aikman, Charles M., 183, St. Vincent Street, Glasgow.
 Aikman, Thomson, jun., 5, Prince's Square, Glasgow.
 Aitken, Dr. A. P., 57, Great King Street, Edinburgh.
 Aitken, J. B., Gerard's Fold Chemical Works, Widnes.
 Akitt, Thomas, 3, Victoria Road, Lenzie, N.B.
 Albright, G. S., The Elms, Park Road, Edgbaston.
 Albright, W. A., Mariemont, Birmingham.
 Aldrick, Edwin John, 15, Charles Street, Millwall, E.
 Alexander, J. O., 11, Avenue Road, South Norwood Park, Surrey.
 Alexander, W. T., 20, Booth Street, Moseley Street, Manchester; and Crummock Bank, Victoria Crescent, Eccles.
 Allan, Jno., 2, Crane Court, Fleet Street, London, E.C.
 Alldred, C. H., 6, Heavitree Road, Plumstead Common, Kent.
 Allen, A. H., Sydenham Cottage, Park Lane, Sheffield.
 Allen, G. J., Ivy House, Bolton Road, Pendleton, Manchester.
 Allen, J., 164, Upper North Street, Poplar, London, E.
 Allen, R. L., Roseligh, Heaton Chapel, near Stockport.
 Allen, Walter S., 13, Beacon St., Boston, Mass., U.S.A.
 Allen, Wm., Evenley Hall, Brackley, North Hants.
 Allen, Wm. N., 2, Chesnut Street, Philadelphia, Pa., U.S.A.
 Allender, G. M., Stammerham, Horsham, Sussex.
 Allhosen, A., Gateshead-on-Tyne.
 Allhusen, Wilton, 102, Quay Side, Newcastle-on-Tyne.
 Allibon, G. H., Mewburn, Litherland Park, near Liverpool.
 Allott, J. B. Messrs. Manlove, Allott, and Co. Ltd., Nottingham.
 Alpiar, Agop, Smyrna, Asia Minor.
 Alsberg, M. (Sondheim, Alsberg, & Co.), P.O. Box 2437, New York, U.S.A.
 Anderson, Eugene E. J., Gasworks, Maryhill, by Glasgow.
 Anderson, Geo. B., Victoria Square, Felling-on-Tyne.

 Wallace, Robert, 117, Albert Bridge Road, Belfast, Ireland.
 Waller, Dr. E., School of Mines, Columbia College, 50th Street, 4th Avenue, New York, U.S.A.
 Walsh, F. T., Hamilton Printworks, Lowell, Mass., U.S.A.
 Walsh, P. H., 13, Penny Street, Blackburn, Lancashire.
 Waltham, T., Brewery, Stockwell, London, S.W.
 Walton, Cornelius, 12, Craven Street, Claring Cross, W.C.
 Wansbrough, E. G. L., 5, Pond Street, Hampstead, N.W.
 Ward, G., Messrs. Hirst, Brooke and Hirst, Leeds.
 Ward, Geo., c/o T. Howard Lloyd & Co., 86, High Street, Leicester.
 Ward, Howard Chas., Yeatton, Hordle, Lymington, Hants.
 Ward, Thos., Brookfield House, Northwich.
 Wardale, J. D., Redhugh Engine Works, Gateshead-on-Tyne.
 Warden, Dr. C. J. H., Medical College, Calcutta, India.
 Warington, Robt., Harpenden, Herts.
 Warne, Thos., 118, Wednesbury Road, Walsall.
 Warner, H. G., c/o Wallis & Milestone, Garrett Laue, Wandsworth, S.W.
 Warren, Fiske, 220, Devonshire Street, Boston, Mass., U.S.A.
 Warren, Jno. Davis, 137, High Holborn, London, W.C.
 Warren, T. T. P. Bruce, Tanworth Villa, Earham Grove, Forest Gate, Essex.
 Warwick, J. F., The Brewery, Newark-on-Trent.
 Waterfall, W. B., c/o Avon Manure Co., Bristol; and (Journals) Thirlmere, Clavering Road, Redland, Bristol.
 Waterhouse, Colonel Jas., 14, Wood Street, Calcutta, India.
 Waters, Edw. A., c/o Hyderabad Deccan Co., Secunderabad, Deccan, India.
 Watson, Chas., Walsden Chemical Works, near Todmorden.
 Watson, D., 244, Great Clowes Street, Manchester.
 Watson, Eric E., 13, Kingsmead Road, Oxtou, Birkenhead.
 Watson, G. jnn., 16, East Nelson Street, Whitevale, Glasgow.
 Watson, J. Cecil, c/o Daniel Lee & Co., Castleton, Manchester.
 Watson, Jno., Cement Works, Gateshead-on-Tyne.
 Watson, Jno., Laboratory, Newcastle Chemical Co., Gateshead-on-Tyne.
 Watson, Jno., 8, Newman Street, Victoria Docks, E.
 Watson, W. H., Laboratory, The Folds, Bolton.
 Watt, A., 89, Hartington Road, Sefton Park, Liverpool.
 Watts, A. J., 130, Caixa, Pernambuco, Brazil.
 Watts, Chas. W., Corporation Gasworks, Belfast.
 Watts, Sydney E., Tyne Brewery, Newcastle-on-Tyne.
 Webb, Saml. G., c/o W. Pilkington & Son, Widnes.
 Webb, Wm. Hubert, Randalstown, co. Antrim, Ireland.
 Webber, Geo. W., Oswald Hill, Broomhill Drive, Partick, Glasgow.
 Weber, Carl Otto, 1, Rectory Road, Crumpsall, Manchester.
 Webster, C. S. Stanford, Malvern House, Redland, Bristol.
 Webster, Wm. jnn., The Grove, Belmont Hill, Lee, S.E.
 Weightman, John F., c/o Powers & Weightman, Philadelphia, Pa., U.S.A.
 Weir, Surgeon-Major P. A., Opium Agency, Ghazipur, N.W.P., India.
 Weldon, Ernest, 64, Noel Street, New Basford, Nottingham.
 Wells, G. I. J., Kinderton Lodge, Middlewich, Cheshire.
 Wells, John, 33, Northampton Square, Clerkenwell, E.C.
 Welsh, Jas., Kinder Printworks, Hayfield, near Stockport.
 Welsh, Thos. L., 51, St. Vincent Crescent, Glasgow.
 Welsh, W., Holt Town, Manchester.
 Werner, Emil A., 5, Church Avenue, Rathmines, Dublin.
 Wessel, Carl, Bernburg, Anhalt, Germany.
 Wesson, David, The W. J. Wilcox Lard and Refining Co., Guttenberg, N.J., U.S.A.
 West, John, Barfield House, Didsbury, Manchester.
 Westmoreland, J. W., 25, Park Square, Leeds.

- Weston, Wm., H.M. Dockyard, Portsmouth.
 Wetter, Jasper, 433, Strand, London, W.C.
 Wetzel, H. A., Box 470, Detroit, Michigan, U.S.A.
 Whalley, L. J. de, 26, Park Place, Greenwich, S.E.
 Wheeler, Wm. E., Cumberland House, Meynell Road, South Hackney, N.E.
 Whelan, Edwin J., Star Chemical Works, Wandsworth Bridge Road, Fulham, S.W.
 Whewell, Wm., Irwell House, Dumers Lane, Radcliffe, near Manchester.
 Whiffen, T., Lombard Road, Battersea, London, S.W.
 Whiffen, T., jun., Lombard Road, Battersea, London, S.W.
 Whiffen, W. G., Lombard Road, Battersea, London, S.W.
 Whitaker, H. L., Condong Sugar Mill, Tweed River, New South Wales.
 Whitaker, Thorp, Messrs. E. Ripley & Sons, Bradford, Yorks.
 White, A., Horton Field, West Drayton, Middlesex.
 White, A. D., Avenue House, West Drayton, Middlesex.
 White, Henry, 8, Brown Street, Masboro', Rotherham.
 White, Jos. W., Halebank, near Widnes.
 White, J. Campbell, 7, West George Street, Glasgow.
 White, P. T., Castle Street, Saffron Hill, London, E.C.
 White, W. H., Killingworth House, Killingworth, Newcastle-on-Tyne.
 Whitehouse, Enoch, 513, Coventry Road, Smallheath, Birmingham.
 Whitelaw, A., 87, Sydney Street, Glasgow.
 Whiteley, Geo., Victoria Lead Works, Bardett Road, Limehouse, E.
 Whiteley, Jno. W., 210, North Hill Street, Prince's Road, Liverpool.
 Whiteley, R. Lloyd, University College, Nottingham; Journals to 13, Bowers Avenue, Woodborough Road, Nottingham.
 Whittaker, C. J., Globe Chemical Works, Church, near Acreington.
 Whittaker, Thos., 22, Delaunays Road, Higher Crumpsall, Manchester.
 Whowell, F., Carr Bank, Tottington, Bury, Lancashire.
 Wickens, B. Foster, 183, Queen Street, Cheapside, London, E.C.
 Wigg, C., Hoole Bank, Chester.
 Wigg, G. L., Runcorn.
 Wigg, Walter J., Old Quay Copper and Alkali Works, Runcorn, Cheshire.
 Wiggin, W. W., Wiggin Street, Birmingham Heath, Birmingham.
 Wightman, C., 1, Fenchurch Avenue, London, E.C.
 Wild, Eugene.
 Wilde, T., Penclawdd, near Swansea.
 Wiley, M. W., Billsdale House, York Road, West Hartlepool.
 Wilkie, T. M., Nobel Co.'s Works, Stevenston, Ayrshire N.B.
 Wilkin, Walter H., Appold Street, Finsbury, E.C.
 Wilkinson, J. B., Tong Street, Dudley Hill, Bradford, Yorks.
 Will, W. Watson, The Laurels, Galveston Road, Putney, S.W.
 Williams, D., Sutton Alkali Works, St. Helens.
 Williams, Edward, Folly Farm, Warrington.
 Williams, Geo. G., 624, South 24th Street, Philadelphia, Pa., U.S.A.
 Williams, J. W., 6, Giltspur Street, London, E.C.
 Williams, Rowland, 28, Pall Mall, Manchester.
 Williams, Rupert Greville, P.O. Box 35, Albany, N.Y., U.S.A.
 Williams, T., 3, York Buildings, 14, Dale Street, Liverpool.
 Williams, T. Howell, 10, Ascham Street, Kentish Town, N.W.
 Williams, Prof. W. Carleton, Firth College, and 33, Bromsgrove Road, Sheffield.
 Williams, W. Collingwood, 44, Mulgrave Street, Liverpool.
 Williams, W. J., 623, Market Street, Camden, N.J., U.S.A.
 Williamson, Robt., Cleveland Chemical Works, Middlesbrough.
 Wills, G. S. V., Southwood, Croham Road, South Croydon.
 Wills, J. Lanson, 206, Albert Street, Ottawa, Canada.
 Wilson, A., The Firs, Norton, near Stourbridge.
 Wilson, Alf., c/o Messrs. J. and E. Sturge, 18, Wheeley's Lane, Birmingham.
 Wilson, Anthony W., 20, Westcott Street, Hull.
 Wilson, Cecil H., 656, Grimesthorpe Road, Sheffield.
 Wilson, C. J., 19, 11th Queen Street, Westminster, S.W.
 Wilson, David, jun., Carbeth, Killarn, by Glasgow.
 Wilson, Frank, The Brewery, Castle Street, Long Acre, London, W.C.
 Wilson, Gordon, jun., Crestone, Saguache Co., Colorado, U.S.A.
 Wilson, G. E., The Chemical Works, Oldbury, near Birmingham.
 Wilson, Jno. A., South 20th and Mary Streets, Pittsburgh, Pa., U.S.A.
 Wilson, Jno. Ed., Wyddrington, Edgbaston, Birmingham.
 Wilson, Jno., Redhough Chemical Works, Gateshead-on-Tyne.
 Wilson, Jos. A., Crossfields, Tottington, near Bury, Lancashire.
 Wilson, J. H., 6, Fenchurch Buildings, E.C.
 Wilson, J. Millar, Ridley Park, Delaware Co., Pa., U.S.A.
 Wilson, R. H., Egglecliffe, Yarm-on-Tees.
 Wilson, Dr. W. H., Presidency College, Madras.
 Wilson, Wm. Robt., 110, Long Acre, London, W.C.
 Wilson, W. W., Chirnside Villa, Droydsden, Manchester.
 Wilson, Wm., Journals to Delhi, India; Subscription c/o Clark, Wilson, & Co., 155, Fenchurch Street, E.C.
 Wilton, Geo., Tar Works, Beekton, E.
 Wilton, Jno., Clydesdale, Norwich Road, Forest Gate, Essex.
 Wilton, Thos., Winsor House, Beekton, E.
 Windus, W., 15, Vyvyan Terrace, Clifton, Bristol.
 Wingham, A., 3, Villa Road, Brixton, S.W.
 Winsor, P. J., Wyck House, Bebbington, Cheshire.
 Winsloe, H., Messrs. Tennant & Co., 49, Fankauer Street, Manchester.
 Winstone, A. B., 7, Gray's Inn Square, London, W.C.
 Winstone, E. H., 2, Victoria Mansions, Victoria Street, London, S.W.
 Wire, A. P., 1, Scatillas, Von Birkbeck Road, Leytonstone, E.
 Wise, Jno. B., 190, Bellfield Street, Glasgow.
 Wishart, Jno., 39, St. Vincent Place, Glasgow.
 Witt, Dr. Otto N. E., 33, Lindenallee, Westend, Charlottenburg, Berlin.
 Wolfenden, S., Wellington Terrace, Cowley Hill, St. Helens.
 Wollner, Dr. Robt., c/o Schamer, Noack, & Co., Billwärders a. d. Bille, Hamburg, Germany.
 Womersley, P. B., Lynnhead, Wainstead, Essex.
 Wood, C. H., 46, Lorraine Road, Holloway, London, N.
 Wood, Ebenezer, Stephenson Street, Canning Town, E.
 Wood, E. T., Brinscall, Chorley, Lancashire.
 Wood, Jas., Stockwith-on-Trent, Gainsborough.
 Wood, Joseph, Brinscall, near Chorley, Lancashire.
 Wood, J. Turney, Hound Road, West Bridgeford, Nottingham.
 Wood, Milton R., 33, Oakland Avenue, Brooklyn, N.Y., U.S.A.
 Wood, Robt. B., Dalquhurn Works, Renton, N.B.
 Wood, Wm., 124, Chaussée de Turnhout, Antwerp, Belgium.
 Wood, W. C., Rosshead, Alexandria, Dumbartonshire.
 Woodcock, R. C., American and Continental Sanitas Co., 636-642, West 55th Street, New York, U.S.A.
 Woodham, Kingston G., 45, Parsonage Road, Withington, Manchester.
 Woodhead, Jas., Ashfield Terrace, Slaithwaite, near Huddersfield.
 Woodland, J., 173, Marylebone Road, London, N.W.
 Woodman, Durand, 80, Beaver Street and 127, Pearl Street, New York, U.S.A.

THE JOURNAL

OF THE

Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 1.—Vol. X.]

JANUARY 31, 1891.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2/6.

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.

COUNCIL FOR YEAR ENDING JULY, 1891.

President: E. Rider Cook.

Vice-Presidents:

Sir Lowthian Bell, Bart., F.R.S.	Ludwig Mond.
R. Forbes Carpenter.	Dr. Hugo Müller, F.R.S.
Prof. James Dewar, F.R.S.	B. E. R. Newlands.
James Duncan.	Dr. W. H. Perkin, F.R.S.
David Howard.	Dr. Edw. Schunck, F.R.S.
S. H. Johnson.	J. C. Stevenson, M.P.

Ordinary Members of Council:

A. H. Allen.	Prof. R. Meldola, F.R.S.
L. Archbutt.	E. K. Muspratt.
S. B. Boulton.	T. L. Patterson.
Jno. Brock.	Jno. Pattinson.
Jno. Calderwood.	Jno. Spiller.
H. Grimsshaw.	T. W. Stuart.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Dr. Ferdinand Hurter.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

Sir F. A. Abel, F.R.S.	Prof. A. K. Huntington.
A. H. Allen.	F. Hurter, Ph.D.
L. Archbutt.	Ivan Levinstein.
G. H. Bailey, D.Sc., Ph.D.	Prof. R. Meldola, F.R.S.
Joseph Bernays, M.I.C.E.	Ludwig Mond.
H. Brunner.	E. K. Muspratt.
Prof. Frank Clowes, D.Sc.	B. E. R. Newlands.
W. Y. Dent.	C. O'Sullivan, F.R.S.
Prof. Jas. Dewar, F.R.S.	John Pattinson.
John Heron.	W. H. Perkin, Ph.D., F.R.S.
D. B. Hewitt, M.D.	Sir H. E. Roscoe, M.P., F.R.S.
David Howard.	John Spiller.
Prof. J. J. Hummel.	A. Norman Tate.
	Thomas Tyrer.

Editor:

Watson Smith, University College, London, W.C.

NOTICES.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January and May 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

LIST OF MEMBERS ELECTED, 23rd JANUARY, 1891.

- Arrol, Jas., jun., João Branco, Marahu, Bahia, Brazil, works chemist.
- Atkins, Chas. E., East Ham House, East Ham, Essex, chemical student.
- Ball, Jno. B., 1, Gresham Buildings, Basinghall Street, E.C., chartered accountant.
- Black, Jas. W., 11, Kirkdale, Sydenham, S.E., manufacturing chemist.
- Bloomer, Fred. J., 7, Boundaries Road, Balham, S.W., technical chemist.
- Brown, A. Selwyn, 43, Portsdown Road, Maida Vale, W., civil engineer.
- Caines, G. S. A., 7, Rochester Terrace, Camden Road, N.W., analytical chemist.
- Candy, F. Pullen, 56, Nightingale Lane, Balham, S.W., engineer.
- Carden, Albert J., Lea Valley Distillery, Warton Road, Stratford, E., distiller.
- Clutton, Jno. H., Purton House, Burry Port, R.S.O., Carmarthenshire, assayer.
- Colby, Albert L., Bethlehem Iron Co., Bethlehem, Pa., U.S.A., head chemist.
- Colman, Harold G., 12, St. John's Terrace, Waltham Green, S.W., chemist.
- Cooper, Walter J., High Street, Mitcheldean, near Gloucester, cement works manager.
- Corner, Hurry, P.O. Box 31, Jersey City, N.Y., U.S.A., manager of creosoting works.
- Couche, Chas. W., c/o Runcorn Soap and Alkali Co., Weston, Runcorn, technical chemist.
- Craven, Jno., jun., Smedley Lodge, Cheetham, Manchester, chemist.
- Danziger, Henry, 31, Camp Street, Lower Broughton, Manchester, chemical student.
- Ellison, Henry, Platt Lane, Checkheaton, Yorks, manufacturing chemist.
- Field, Wm., Eddington, St. Kilda, Melbourne, Victoria, chemist.
- France, Jos., 43, Church Street, Rotherham, Yorks, chemical merchant.
- Frankfeld, Dr. Henry, 7, Hope Street, Higher Broughton, Manchester, chemist.
- Gair, Wm., c/o W. C. Tripler, Coquimbo, Chili, analyst.
- Galt, Hugh Allen, Kalion Chem. Co., Philadelphia, Pa., U.S.A., chemist.
- Geisler, Dr. Jos. F., 6, Harrison Street, New York, U.S.A., consulting chemist.
- Gibb, Thos., 11, Forest Drive, Leytonstone, Essex, chemist.
- Gimingham, Edw., Stamford House, Northumberland Park, Tottenham, N., superintendent electric light works.
- Greaves, J. A. R., Old Rectory, Grappenhall, Cheshire, brewer.
- Green, Samuel, 28 and 29, St. Swithin's Lane, London, E.C., chemical auctioneer.
- Hanson, John, Hightfield Villa, Belle Vue, Wakefield, manufacturing chemist.
- Hart, H. W., Turkey Lane, Queen's Park, Manchester, analytical chemist.
- Hartog, Philip J., Owens College, Manchester, Berkeley Fellow of Owens College.
- Hausknecht, Dr. Willy, Carbonic Acid Gas Co., Limited, Lea Bridge Road, Clapton, E., chemist.
- Himman, Bertrand C., c/o Ironclad Manufacturing Co., 929, Flushing Avenue, Brooklyn, E.D., U.S.A., chemist.
- Hovenden, F., Glenlea, Thurlow Park Road, West Dulwich S.E.
- Hunt, Richard, Reform Club, Liverpool.
- Innes, Murray, Box 129, Alameda, California, U.S.A., technical chemist.
- Jackson, Vincent, 10, Chorley Old Road, Bolton, Lancashire, dyer.
- Joslin, Omar, c/o Swift and Co., Union Stock Yards, Chicago, Ill., U.S.A., chemist.
- Kay, Percy, Technical College, Bradford, Yorks, demonstrator in chemical department.
- Kings, Jas. Edw., Know Mill Printing Co., Limited, Entwistle, near Bolton, technical chemist.
- Knabe, F., 329, Ashton New Road, Clayton, near Manchester, chemist.
- Lenox, Lionel R., Lehigh University, South Bethlehem, Pa., U.S.A., instructor in chemistry.
- Lindemann, G., Morkenstrasse 90, Altona, near Hamburg, Germany, chemist.
- Lindley, Hubert E., 13, St. Bartholomew Road, Camden Road, N., analytical chemist.
- Linfoot, J., Rhodes Works, Middleton, Lancashire, chemist.
- Loewenthal, Dr. R., 239, Moss Lane East, Manchester, chemist.
- Macadam, Herb. E., The Lake, Snarebrook, Essex, assistant manager, manure works.
- Maclvor, R. W. Emerson, 51-53, Handforth Road, Clapham Road, S.W., consulting chemist.
- Mann, Jno. C., 626, Barking Road, Plaistow, E., chemist.
- Marshall, Dr. Hugh, Chemistry Department, University of Edinburgh, assistant to Professor of Chemistry.
- Martin, Chas. D., 106, Addison Road, Heaton, Newcastle-on-Tyne, chemical plant manufacturer.
- Meyer, Max, The Cedars, Sutton, Surrey, chemist.
- Parker, Edw., Laburnum House, Rushford Park, near Manchester, chemist.
- Price, T. Spiers, 16, Mark Lane, London, E.C., secretary.
- Quinn, J. Cardwell, Gateacre House, Gateacre, Liverpool, chemical student.
- Sharpe, Granville H., 11 and 12, Great Tower Street, London, E.C., chemist.
- Skilton, C. F. E., c/o Ind. Coope, and Co., Burton-on-Trent, brewer.
- Smith, Edgar B., Prince Regent's Wharf, Silvertown, E., works chemist.
- Smith, John, Sutton Copper Works, St. Helens, Lancashire, manager.
- Stanger, W. Harry, Broadway Testing Works, Westminster, S.W., engineer.
- Thomson, Jas. M., Royal Gunpowder Factory, Waltham Abbey, Essex, chemist.
- Thomson, Dr. Murray, 44, Victoria Road, Gipsy Hill, S.E., retired Professor of Chemistry.
- Wallace, Jno. Stewart, 11, Queen Victoria Street, London, E.C., engineer.
- Wansbrough, E. G. L., 5, Pond Street, Hampstead, N.W., pharmaceutical chemist.
- Watson, Jno., 8, Newman Street, Victoria Docks, E., assistant analytical chemist.
- Weber, Dr. Carl O., 1, Rectory Road, Crumpsall, Manchester, chemist.

CHANGES OF ADDRESS.

- Allison, G. H., 10 Seaview, Mewburn, Litherland Park, near Liverpool.
- Atcherley, Dr. R. J., Retain Journals until further notice.

Bainbridge, H. W., 1/o Solihull; 8, George Street, Manchester Square, London, W.
 Bartholomew, G., 1/o Ilford Park; Fairfield Works, Bow, E.
 Beadle, Clayton (subs.), c/o W. Joyson and Sons, St. Mary Cray, Kent, and (Journal) Beadonwell, Belvedere, Kent.
 Beames, Edw., 1/o Brenehley; Motlands, Paddock Wood, Kent.
 Bewick, T. Burrell, 1/o Hebburn; Suffolk House, Lawrence Pountney Hill, E.C.
 Billing, H. S., Journals to c/o Burnard and Alger, Limited, Plymouth Chemical Works, Plymouth.
 Blake, F. C., 1/o Mansfield Valley; 61, 4th Avenue (P.O. Box 1062), Pittsburgh, Pa., U.S.A.
 Borland, W. D., 1/o London; Beacon Lodge, Green Street Green, near Dartford, Kent.

2. "The Products of Checked Combustion."

April 20th.—Mr. W. P. Rix. "Stoneware: and its Application to Chemical Apparatus."

May 6th. Professor Dewar, F.R.S., and Mr. Boyerton Redwood, F.R.S.E. "A Process for the Conversion of Heavy Mineral Oils into Lighter Hydrocarbons suitable for Illuminating and other purposes."

June 1st. Dr. W. S. Squire. "The Artificial Production of Cold theoretically and practically explained."

Meeting held Monday, January 5th, 1891.

MR. THOS. TAYLOR IN THE CHAIR.

THE BASIC PROCESS AS APPLIED TO COPPER SMELTING.

BY PERCY C. GILCHRIST, A.R.S.M.

AROUND from the great advantages which ensue from the replacement of the ordinary silicious linings of steel-smelting furnaces by a lining composed of basic material, when phosphoric pig iron has to be converted, it might reasonably be expected that the substitution of a basic lining for the silicious lining hitherto employed in copper-smelting furnaces, should also be followed by similarly advantageous results, especially when the cuprififerous material to be treated contains any notable percentage of arsenic or antimony. It was not, however, until comparatively recently that the author had the opportunity of practically testing whether or no any such advantage really resulted in practical working.

In the case of steel manufacture, the result aimed at in substituting a basic lining for the acid was well defined, viz., the removal of phosphorus, a problem incapable of solution in acid-lined furnaces, owing to the acid nature of the slags necessarily formed with such linings, but which was readily accomplished so soon as the presence of a basic lining in the furnace allowed of a basic slag being formed

and maintained. No such direct improvement, however, was to be looked for in the case of copper smelting, as the only deleterious element occurring with any frequency in crude copper, viz., arsenic, can be very perfectly eliminated in the acid lining at present made use of. A careful study, however, of the composition of copper roaster and refinery slags reveals the facts that, unlike steel slags from acid practice, the copper slags formed during the removal of the arsenic are basic and not acid in character, the basicity being chiefly due to the presence of copper oxide in quantity more than sufficient to neutralise the silica, which latter, in the roaster and refinery furnace, originates almost wholly from the sand or clay used to form the furnace bath. Lime or lime and soda ash are used very generally in the ordinary sand-lined refinery, but the quantity which can be added without detriment to the lining is not large, and does not compensate for the large amount of silicious material which is dissolved away from the sides of the furnace. It was therefore rather in the direction of lessened oxidation, and therefore increased yield, that the author expected improved results by the use of basic linings and more calcareous slags in copper smelting.

In May 1889 the technical adviser of one of our largest copper-smelting companies was exceedingly anxious to make a trial of a basic lining in one of their roaster furnaces. This lining was accordingly put in and is still in perfect condition. The results obtained with this first lining were so satisfactory that at the present time the company have nine roaster furnaces at work treating arsenical "metallic bottoms" and white metal. The process has been very thoroughly examined by the technical advisers of the company, and the author has pleasure in acknowledging the very valuable assistance rendered by these gentlemen. As the old roaster furnaces require renewing, they are being rebuilt with basic hearths, so that, shortly, probably all the roaster furnaces employed at these works will be furnished with basic linings. Further on in this paper will be found some figures showing the comparative yields obtained from a basic and an acid roaster working side by side, together with analyses of the blister and slag obtained in each case.

These roaster furnaces have cast-iron bottom plates, underneath which a free current of air circulates; by this means the bottom of the furnace is kept cool, it likewise prevents the possibility of any fusing action taking place between the basic hearth and its support, which might be the case were the basic hearth built directly upon the ordinary silica arch. The basic material is ground and mixed with tar in the usual way, and the furnace bottom is formed by throwing this material into the hot furnace and burning it on in layers, well heating down each separate layer and giving it fire for some hours before applying a fresh layer. It usually takes four or five days to burn on a bottom in this way. When the bottom is properly shaped it should be seasoned by melting on it some rich copper precipitate or good blister copper. It was at first considered that the basic hearth absorbed less copper than the ordinary sand ones, but there appears to be very little, if any, difference between them, much depending on the way the bottom is formed and seasoned. The tap-hole of the furnace is shut by throwing a little basic material against it from the inside. In other respects the working of the furnace is conducted in the usual way. After each charge any slight repairs that the banks may require are made by throwing some basic material against the place needing repair; the repairs required are, however, very slight in comparison with an acid furnace, the tendency being for the furnace banks to grow rather than to cut away.

TREATMENT OF ARSENICAL METALLIC BOTTOMS IN BASIC-LINED FURNACES.

The mineral in use at these works is arsenical, and although in the crude ore the arsenic is not high, yet when the ore is allowed to oxidise in heaps and the copper afterwards precipitated from the solution, obtained by lixiviating the ore, arsenic is concentrated in the precipitated copper to a considerable extent, the resulting precipitate usually containing some 3 to 3½ per cent. of arsenic. Very

large quantities of this precipitate are treated. It is added to the mixture of slag and metal charged into the smelting furnace, and according to the amount of precipitate so added to the charge, more or less of the product tapped from the smelter consists of impure copper, known as "metallic bottoms." An average analysis of these bottoms gives:—

	Per Cent.
Copper.....	83 to 87
Arsenic	5 to 7
Sulphur.....	1 to 3
Iron	0·5
Lead.....	3 to 5
Silica	0·5

It is in the conversion of these metallic bottoms into blister copper containing under 1 per cent. of arsenic that the basic furnaces have shown themselves to the greatest advantage. The following comparative statement of the results obtained when treating some 400 tons of such arsenical bottoms in acid- and basic-lined furnaces will best show the large increase in yield which results from the lessened oxidation in the basic-lined furnaces.

COMPARATIVE STATEMENT OF METALLIC BOTTOMS ROASTED, RESPECTIVELY, IN BASIC- AND SAND-LINED FURNACES.

	Basic Furnaces.	Average Sand Furnaces.
	t. c. q.	t. c. q.
Metallic bottoms used during 12 weeks ending September 30th, 1889.....	400 10 0	400 10 0
Average analysis 84·52 per cent. copper and 5·91 per cent. As		
59 charges made, averaging per charge...	6 15 1	6 15 1
Blister copper produced from same.....	323 6 2	191 15 0
Average produce per charge.....	5 9 2	3 5 0
Average arsenic 1·11 per cent.		
Slag made from above charges	102 16 3	221 15 0
Average weight per charge	1 14 3	3 15 0
Average copper percentage.....	25%	55%
Time occupied per charge, including fettling, charging, &c.	294 hours.	38 hours.

Calculating from the above figures, we find that taking the real copper in the "metallic bottoms" at 84·5 per cent., and the real copper in blister at 98·5 per cent., there was obtained in the form of blister 94 per cent. of the real copper from the basic furnace and 56 per cent. of the real copper from the acid furnace, showing a gain of 38 per cent. in favour of the basic furnace. The real copper in the slag works out to 25 tons 14 cwt. from the basic furnace, and 121 tons 19 cwt. from the acid furnace. The tonnage figures given in the above table are as correct as the weighers could get them and are taken from the weighers' books. The deductions drawn from them are not absolutely correct, as they show a slight gain of copper in the case of the basic furnace. This is easily accounted for by the analytical figures given for the copper percentages being averaged over a large quantity.

The following is an example of a charge of metallic bottoms worked down into blister in a basic roaster furnace, together with analyses by Mr. E. Riley of the slags skimmed off:—

PARTICULARS OF WORKING CHARGE NO. 79 IN NO. 27 BASIC FURNACE.

Charged Monday, 4th November 1889, at 3 p.m.

Seven tons of metallic bottoms, containing 87·4 per cent. of Cu and 4·6 per cent. As.

Six cwt. of lime added with the charge.

Charge under air for five hours, clear off bottom at 10 p.m. = 10 hours.

Sample No. 1	10 0 p.m.	1st skimming	c. q. lb. 9 1 6
No. 2	11 20 p.m.	2nd "	3 1 0
No. 3	5 30 a.m.	3rd "	7 2 8
Sample of blister gave at this time 1·42 per cent. arsenic.			
"	7 0 a.m.	Six shovels of lime added.	
No. 4	10 15 a.m.	4th skimming	4 2 16
Sample of blister gave at this time 1·36 per cent. arsenic.			
Six shovels of lime added.			
No. 5	10 45 a.m.	5th skimming	2 1 8

The furnace was then tapped, the blister giving 1·36 per cent. arsenic.

Weight of blister tapped.....	t. c. q. lb. 6 19 0 6
Weight of slag tapped	1 7 0 20
Lime used	6 6 0 20
Fettling used, 12 per cent. tar....	0 2 1 6
(60 per cent. of this for tap-hole.)	

The analyses of the different skimmings of slag are as follows:—

	1.	2.	3.	4.	5.
Silica	18·62	5·70	6·30	6·73	6·76
Lime.....	19·20	14·80	17·57	23·38	20·16
Ferrous oxide.....	7·35	2·42	3·45	2·16	2·06
Cuprous sulphide	1·25	Trace.	8·50	1·50	Trace.
Cuprous oxide.....	8·76	30·12	23·30	19·10	27·74
Arsenic acid.....	11·70	23·07	20·80	35·55	31·30
Lead oxide.....	24·00	12·44	7·16	2·20	2·20
	90·88	88·55	86·98	90·62	90·22

By calculation from the weight and copper percentage of each slag drawn, it will be found that the total real copper contained in the 1 ton 7 cwt. of slag drawn is 5 cwt. 23 lb., which equals on the real copper contained in the 7 tons of bottoms charged, 4·1 per cent. of copper slagged.

In addition to the largely increased yield of blister obtained from the basic furnace over the sand-lined furnace when treating metallic bottoms, there is a further advantage, viz., that these metallic bottoms have a most deleterious effect upon the sand lining of the furnaces, the bottom nearly always requiring repair after three or four days' working. It is partly owing to this fact that the production of these metallic bottoms (except in small quantities accidentally) has nearly ceased in England, except at the works of one or two firms. Other firms usually prefer to throw the copper back from the state of precipitate to sulphide in the smelting furnace, and this is no doubt the more preferable way where no basic-lined furnace is available. But from the results given above, where large quantities of arsenical precipitate have to be treated, the formation of metallic bottoms, with subsequent treatment in a basic-lined roaster furnace, is, in the author's opinion, by far the more economical method of procedure, especially as the metal tapped simultaneously from the smelting furnace with the copper bottoms is far lower in arsenic and other impurities than when no copper bottoms are allowed to form. In practical working, the whole of the smelter charge, consisting of a mixture of metallic bottoms with more or less white or purple metal attached, is charged into the basic roaster furnace, without any stripping or separation of the two. The results given above, however, were made on charges of metallic bottoms alone, the metal having been separated previous to use.

TREATMENT OF WHITE OR PIMPLE METAL IN THE BASIC ROASTER FURNACE.

Although it has been found, when working in a basic-lined furnace, that the greatest advantage results when treating metallic bottoms, yet a very considerable gain in output is obtained when treating white or pimple metal.

The following comparative results show about what this gain amounts to, the figures in each case being the totals of six consecutive charges, taken at random from the weigher's books:—

Furnace.	Metal Charged.	Blister Tapped.
	t. c. q.	t. c. q.
Six charges from first basic furnace.	57 0 0	39 15 3
" " second " " "	57 0 0	37 15 1
" " third " " "	57 0 0	39 3 3
" " fourth " " "	57 0 0	32 10 6
" " fifth " " "	57 0 0	38 13 2
" " first acid furnace	63 0 0	34 19 2
" " second " " "	63 0 0	31 2 0

These figures show a gain in the output of about 13 per cent. in favour of the basic furnace. Another series of comparative charges of white metal in sand- and basic-lined furnaces were made, of which the results are shown in tabular form below. It will be seen that these also show a large gain in output in favour of the basic furnace:—

COMPARATIVE STATEMENT OF WHITE PIMPLE METAL ROASTED RESPECTIVELY IN BASIC AND SAND-LINED FURNACES.

	Basic-Lined Furnaces.	Sand-Lined Furnaces.
	t. c. q.	t. c. q.
White pimple metal used during two weeks ending October 14th, 1889.....	87 0 0	87 0 0
Average analysis 76·16 per cent. copper, and 1·68 per cent. As		
11 charges made, average per charge ..	7 18 0	7 18 0
Blister copper produced from same	59 6 0	38 10 0
Average produce per charge.....	5 7 3	3 10 0
Average per cent. arsenic, 0·85 per cent.		
Slag made from above charges.....	11 17 2	41 7 0
Average weight per charge.....	1 1 1	3 15 0
Average per cent. copper contents.....	25 per cent.	55 per cent.
Time required per charge, including fettling, charging, &c.,	16 hours	16 hours

Calculating from the above figures, we find that of the real copper charged, 87 per cent. is obtained from the basic furnace, and 57 per cent. from the acid furnace in the form of blister, showing a gain of 30 per cent. in favour of the basic furnace. Of the real copper charged, 1·43 per cent. is found in the basic slag and 31·1 per cent. in the acid slag.

Still another comparative series gave per 100 tons of white metal charged—77 tons real copper, 42 tons from acid furnace and 62 tons from basic of copper as blister, showing per 100 parts of real copper charged a gain of 26 per cent. in favour of the basic.

It should be stated that, owing to the arsenic remaining in the bath when the blister arrives at blister pitch, the copper cannot be at once tapped, as is usual in cases where low arsenical stuff is worked, but it has to remain in the furnace until a test shows the arsenic in the blister to be below 1 per cent. With 10-ton charges in acid-lined furnace this takes on an average nine hours after the bath has become blister. In the basic-lined furnace six hours is found sufficient.

Samples taken from the bath of an acid and basic roaster furnace just as they came blister gave the following results:—

	Basic Furnace.	Acid Furnace.
	Per Cent.	Per Cent.
As in pimple metal charged	2·16	1·71
As remaining in bath at blister	2·22	3·13
As in copper tapped	0·78	0·30
Hours in furnace after becoming blister..	6½	10

The increase of arsenic at blister pitch in the acid furnace shown in the above analysis is, however, probably exceptional.

The following table, giving full details of weights, &c. of six charges of white metal made in a basic roaster and six made in a sand-lined roaster. The following are the analyses by Mr. E. Riley of the metal charged, the blister obtained, and the slag produced from these charges. Samples of each charge and slag were taken, and the samples afterwards mixed as shown below, so as to get for the analysis the average of the six both for the basic and the acid.

	99'57	99'85	100'34	100'62

As the total weight of the slags drawn from the six basic charges is only 14 tons 14 cwt., against 31 tons 17 cwt. from the six acid charges, and as the copper content of the basic slags is, as shown above, less than the acid, it follows, as the yields prove, that the oxidation in the case of the basic furnace is very much less than in the acid furnace, that is a gain in blister of 26 per cent. per 100 parts of real copper charge.

Another white metal charge in the basic roaster, of which the various slags drawn were separately analysed, is as follows :—

Charged Tuesday, 5th November 1889, at 3.30 p.m.
7 tons metal, 77'2 per cent. Cu, 99 per cent. As.
2 cwt. lime thrown on top.

Clear off bottom at midnight, 9 hours.

As regards the removal of antimony in the basic-lined roaster furnace, another firm found as the result of working up in a basic roaster a considerable amount of arsenical stuff, that simultaneously with the removal of 84 per cent. of the arsenic present, they removed also 87 per cent. of the antimony contained in the charge.

For the purpose of testing whether any material chemical difference existed between the blister produced in the basic-lined roaster furnace and that produced in the ordinary sand lining, charges of blister (1) from a basic roaster, and (2) from an acid roaster, were separately refined in the ordinary sand-lined refinery; the following analyses show the results obtained in each case. It will be seen that there is no practical difference between the refined copper produced from the basic blister and that produced from the acid blister when an acid-lined refinery was used.

THE BASIC LINING APPLIED TO COPPER REFINING.

After carefully investigating the results obtained from the substitution of a basic lining in the roaster furnace for the ordinary sand lining, it was resolved to test whether any substantial improvement resulted from a similar change in the refinery furnace.

The margin for improvement in the case of the refinery furnace is far less than in the case of the roaster furnace process; it is therefore still a little uncertain whether the extra cost of the initial basic lining and of the current repairs are compensated for by the slightly increased yield, when making ordinary tough cake. When, however, it is a question, not of making ordinary tough cake, but of producing best selected copper from ordinary arsenical blister (containing about 1 per cent. of arsenic) there is in the author's opinion a very great saving in waste effected by the use of a basic lining in the refining furnace.

The basic refinery has so far been used chiefly for the production of best selected copper from B.S. precipitate only, or from pure blister containing only some .2 to .3 per cent. of arsenic, but some charges have recently been made from blister containing 1 per cent. As, which have been worked down into B.S. ingots with very good results as regards yield, but as might naturally be expected longer time is required. The following is an example of the results obtained when producing B.S. ingots from rich precipitate.

CHARGE A.

	t.	c.	q.	lb.
Charged in rich precipitate	12	13	0	2
" scrap copper	0	5	0	17
Products:—				
B.S. ingots	9	2	1	22
Scrap and moulds	0	18	1	23
Slags, 1st skimming	0	10	0	14
" 2nd "	0	6	2	18
" 3rd "	0	6	0	12
" 4th "	0	8	0	6

The precipitate charged contained 7.7 per cent. of moisture and there was used during the charge 3 cwt. of lime and 2 cwt. of soda ash.

CHARGE B.

The analyses and weights of another charge of good precipitate worked down into B.S. ingots may here be quoted, the analyses in this case being by Mr. Stead of Middlesbrough.

The furnace was charged with 10 tons 2 cwt. 1 qr. of copper precipitate of the following composition, the sample being dried at 212°.

Copper	88.83
Iron	0.69
Arsenic	0.15
Antimony	0.01
Tin	0.01
Lead	0.03
Bismuth	0.06
Sand	1.12
Graphite	0.55
Sulphur	0.06
Phosphoric Acid	0.46
Combined Water	0.88
Oxygen combined	7.15

100.02

Moisture

7.31

The B.S. ingots produced from the above precipitate gave:—

Copper	99.83
Iron	0.02
Nickel	Trace
Zinc	Trace
Lead	Trace
Bismuth	0.03
Antimony	Trace
Tin	Trace
Arsenic	0.068

99.948

The slags drawn were separately sampled and mixed in proportion to the weights drawn, so that the following is the average analysis :—

	Per Cent.
Suboxide of copper	61.36
Oxide of copper	2.74
Lime	6.82
Soda	4.51
Magnesia	2.80
Oxide of manganese	0.14
Protoxide of iron	1.99
Alumina	2.12
Oxide of zinc	0.01
Oxide of bismuth	0.07
Oxide of lead	Trace
Oxide of tin	0.03
Oxide of antimony	0.06
Silica	8.25
Phosphoric acid	1.83
Sulphur	0.17
Carbonic acid	1.28
Arsenious acid	2.30
	<hr/>
	99.51
	<hr/>
Copper	56.64

CHARGE C.

Another precipitate charge, in which the material charged in and refined copper produced were fully analysed by Mr. Riley, gave the following results.

Precipitate charged :—

Metallic copper	99.88
" iron	1.14
" lead	0.03
" bismuth	0.04
Oxygen	5.51
Arsenic	0.26
Phosphorus	0.28
Silica	1.10
Combined water	1.25
Graphitic carbon	Trace
Antimony	Nil
	<hr/>
	99.79

The B.S. ingots produced from the above precipitate had the following composition :—

Copper	99.805
Tin	Nil
Silver	Trace
Bismuth	0.05
Antimony	Nil
Arsenic	Nil
Lead	0.02
Iron	0.03
	<hr/>
	99.961

The analysis of the slag from above charge gave :—

Silica	15.05
Suboxide of copper	25.72
Oxide of iron	18.09
Oxide of lead	0.24
Alumina	7.05
Oxide of manganese	0.68
Lime	19.05
Magnesia	6.33
Arsenic acid	1.53
Phosphoric acid	4.00
Sulphur	0.19
Combined water	0.85
	<hr/>
	99.38
	<hr/>
Metallic copper per cent.	22.84

CHARGE D.

As an example of the results obtainable from the basic refinery when making ordinary tough cake from fairly arsenical blister, the following analyses were made by Mr. Westmoreland. The details of the charge were as follows :—

The charge consisted of 15 tons 9 cwt. 3 qrs. of blister of the following composition :—

	Per Cent.
Copper	98.150
Arsenic	0.770
Antimony	0.067
Iron	0.078
Nickel	0.029
Sulphur	0.002
Phosphorus	Trace
Bismuth	0.025
Lead	0.011
Silver	0.008
	<hr/>
	99.143

The tough cake laded contained :—

Copper	98.870
Arsenic	0.710
Antimony	0.055
Iron	0.059
Nickel	0.021
Sulphur	0.004
Phosphorus	Traces
Bismuth	0.027
Lead	0.023
Silver	0.009
	<hr/>
	99.863

The furnace was not wholly emptied, only some 12 tons being laded out, but the slag was weighed and carefully sampled so that the amount of copper oxidised in the slag is easily got at. The total slag weighed 1 ton 5 cwt. 3 qrs., and had the following average composition :—

Sample dried at 212° F.

Copper	38.15
Oxygen	4.80
Oxide of lead	1.94 = 1.80 % Pb
Oxide of bismuth	0.04
Arsenic acid	2.60 = As 1.70
Oxide of antimony	0.22 = Sb 0.17
Silica	29.84
Peroxide of iron	3.21
Alumina	2.03
Oxide of manganese	0.15
Oxide of nickel	0.22
Lime	12.69
Magnesia	3.00
Sulphuric acid	0.17
Phosphoric acid	Traces
	<hr/>
	99.06

Calculating from the above figures we find that the total real copper which passed into the slag was in this case 9.8 cwt., or per 100 parts real copper charged, 3.2 parts passed into the slag. A similar charge in an acid-lined furnace gave per 100 parts of real copper charged into the furnace 5.1 parts of copper in the slag.

CHARGE E.

Another B.S. charge which was made from blister containing rather a high percentage of arsenic, is given below.

The charge consisted of :—

Blister	Tn cwt. qr. lb.
	8 13 2 25

and 1 cwt. of lime and 3 cwt. of soda ash were used in working down the charge.

The charge was in the furnace for 48 hours, and was laded in the form of B.S. ingots. The products were:—

	Tn. cwt. gr. lb.
Best select ingots	7 18 0 7
Total slag	2 7 1 17

The analyses by Mr. Westmoreland of the blister charged and refined copper obtained are as follows:—

	Blister charged.	Refined Copper.
Copper.....	99.420	99.910
Arsenic.....	1.050	.020
Antimony.....	.020	.007
Iron.....	.155	.050
Nickel.....	.023	.004
Sulphur.....	.017	Nil
Phosphorus.....	Traces	Traces
Bismuth.....	.020	.022
Lead.....	.013	.011
Silver.....	.009	.011
Insoluble silicious matter.....	1.570	..
	99.327	100.005

The different skimmings of slag were separately sampled and then mixed in proportion of the weight of each separate skimming, so that the following is an average analysis of the slag:—

CaO:	
Copper.....	22.53
Oxygen.....	2.83 Per Cent.
Oxide of lead.....	0.60 = Pb 0.56
Oxide of bismuth.....	0.05
Arsenic acid.....	5.15 = As 3.36
Tetroxide of antimony.....	0.20 = Sb 0.14
Silica.....	24.18
Peroxide of iron.....	6.70 = Fe 4.60
Alumina.....	2.90
Oxide of manganese.....	0.30
Oxide of nickel.....	0.13
Lime.....	17.82
Magnesia.....	8.75
Sulphuric acid.....	0.58 (SO ₃)
Phosphoric acid.....	0.13 (P ₂ O ₅)
Carbonic acid.....	1.24 (CO ₂)
Combined water.....	0.73
Soda calculated as Na ₂ O.....	5.33
	100.15

By calculation from the above figures we arrive at the result that from 100 parts of real copper charged, 94 parts were obtained in the form of B.S. ingots and 6 parts passed into the slag.

CHARGES F. AND G.

As the working down of blister rather high in As into B.S. ingots is considered by the author as of considerable importance, the details of two other charges worked in the basic refinery are given:—

	Charge 259.	Charge 265.
	Tn. cwt. gr. lb.	Tn. cwt. gr. lb.
Blister charged.....	7 17 0 6	9 3 0 21
B.S. ingots laded.....	6 18 2 0	7 12 1 21
Scrap and moulds.....	..	1 7 1 17
Total slag drawn.....	2 4 2 2	3 3 0 8

The analyses of these charges by Mr. Stead gave:—

	Blister charged.	
Copper.....	97.50	97.77
Iron.....	0.05	0.04
Arsenic.....	1.95	1.52
Antimony.....	0.02	0.02
Tin.....	0.02	0.02
Lead.....	0.01	0.01
Zinc.....	0.02	0.02
Bismuth.....	0.05	0.06
Sand.....	0.20	0.21
Sulphur.....	0.06	0.07
	99.88	99.74

The B.S. ingots produced had the following composition:—

Copper.....	99.86	99.89
Iron.....	0.02	Trace
Nickel.....	Trace	Trace
Zinc.....	Trace	Trace
Lead.....	Trace	Trace
Bismuth.....	0.03	0.02
Antimony.....	Trace	Trace
Tin.....	Trace	Trace
Arsenic.....	.002	0.05
	99.972	99.96

Mr. Stead informs me that by "Trace" in the above analyses he means under .01 per cent.

An average analysis of the slags drawn from the above charges, each skimming being sampled and mixed in proportion to the weight, gave:—

	Charge 259.	Charge 265.
	Per Cent.	Per Cent.
Suboxide of copper.....	48.42	33.22
Oxide of copper.....	7.77	6.12
Lime.....	10.65	16.32
Soda.....	5.04	4.77
Magnesia.....	3.17	5.81
Oxide of manganese.....	0.18	0.14
Protoxide of iron.....	5.94	4.05
Alumina.....	2.82	6.97
Oxide of zinc.....	0.04	Trace
Oxide of bismuth.....	0.07	0.10
Oxide of lead.....	Trace	Trace
Oxide of tin.....	0.02	0.02
Oxide of antimony.....	0.06	0.05
Silica.....	10.90	16.85
Phosphoric acid.....	0.35	0.53
Sulphur.....	0.18	0.19
Carbonic acid.....	1.30	1.56
Arsenic.....	2.25	2.47
Oxygen, &c. by difference.....	1.14	0.83
	100.00	100.00
Copper.....	49.16	34.67

From the analyses of the blister, and from the weight and copper percentage of the slags drawn, it is found that from 100 parts of real copper charged, 14 parts went into the

slags in charge 259 and 12 parts in charge 263. These high percentages being due to the large amount of arsenic which had to be removed.

From the above example it will be seen that, although the increase of yield when producing tough cake is not so considerable in the refinery furnace as the gain in the roaster furnace is, yet that there is without doubt a considerably lessened amount of oxidation when the refinery is furnished with a basic lining, which is the more apparent the higher the blister charged is in arsenic and the lower the produce laded is required to be, that is, the more the impurities that have to be eliminated by oxidation the greater the saving of copper when using basic linings in the refinery.

Although from the results given, and from a vast number of others which space does not permit of detailing, there is no question about the increase of yield resulting from the lessened oxidation when using basic linings; yet experience has shown that acid-lined furnaces will get rid of impurities as completely as the basic furnaces do, if one does not mind the amount of copper that has to be slagged in so doing. But if one stops each furnace when a similar amount of copper has been wasted in each, it will be found that the purification of the acid charge is very much less complete than in the basic charge.

In order to test what effect a basic lining has on the elimination of antimony and bismuth as compared with their elimination in acid-lined furnaces, a series of charges were made, starting with crude metallic bottoms, which were first worked through the basic- and acid-lined roaster furnaces, the blister obtained from the basic roaster charges refined in a basic-lined refinery, and that from the acid roaster charges in an acid-lined refinery. By this method of procedure it was expected that any difference in the rate of elimination of these and other elements would be magnified by the passage of the material through the two furnaces. The analyses of the bottoms charged in the acid and basic roaster furnaces respectively were as follows, the analyses being made by Mr. Westmoreland:—

Bottoms charged into

	Acid Roaster.	Basic Roaster.
Copper.....	92.32	92.70
Sulphur.....	.95	1.02
Lead.....	.92	.97
Bismuth.....	.062	.06
Arsenic.....	5.09	4.18
Antimony.....	.27	.26
Phosphorus.....	.055	.055
Iron.....	.024	.028
Nickel and cobalt.....	.116	.084
Silver.....	.021	.021
	99.828	99.878

The blister produced from the roaster charges when treating the metallic bottoms of the composition given above contained:—

Blister produced from

	Acid Roasters.	Basic Roasters.
Copper.....	98.46	98.37
Sulphur.....	.004	.017
Lead.....	.018	.046
Bismuth.....	.037	.04
Arsenic.....	.84	.97
Antimony.....	Trace	.063
Phosphorus.....	.069	.012
Iron.....	.022	.019
Nickel and cobalt.....	Trace	.025
Silver.....	.021	.026
	99.828	99.638

The slag produced during the conversion of the metallic bottoms into blister had the following composition, the samples analysed being a mixture from each skimming mixed in proportion of the weight of each slag drawn:—

Sample of Slag drawn from		
	Acid Roaster.	Basic Roaster.
Co ₂ O, Copper.....	37.41	37.17
Oxygen.....	7.23	1.68

It will be seen from the above figures that the acid-lined furnaces have removed the antimony and bismuth more completely than the basic furnaces. This is doubtless due to the thicker more calcareous slags formed in the basic furnaces which prevent the oxidation of the antimony and bismuth more than the thinner cuprifereous slags in the acid furnaces do.

For the acid roaster charges 28 tons of metallic bottoms were treated. These gave from the roaster charges 15 tons 8 cwt. 2 qrs. of slag. For the basic roaster charges 20 tons of metallic bottoms were treated; these gave 5 tons 15 cwt. of slag. From the analyses given above of these slags it may be seen that the real copper slagged was very considerably less in the basic charges than in the acid ones, the actual figures being 34.2 per cent. slagged in the acid roasters, and 11.6 per cent. slagged in the basic roasters.

Summing up, therefore, the results so far obtained in basic copper smelting, it would seem that where the basic process has shown itself to be of most use is in the treatment of highly arsenical material tapped from the smelting furnaces. Such material, being produced from the poorer arsenical precipitates, generally gives a great deal of trouble in the ordinary way of working, with a very high loss of copper in the slags, which necessitates extra labour and expense to rework.

Another very important point to which the basic process shows itself well adapted is in the refining of blister rather high in arsenic (say from 1 to 1½ per cent. or higher) for the purpose of making B.S. ingots.

The action of arsenic upon copper is not, in the author's opinion, altogether similar to the action of phosphorus upon iron. In the case of copper, arsenic up to something like 7 parts in a thousand rather promotes malleability and the expulsion or absorption of oxygen in both basic and acid-lined furnaces. This cannot be said to anything like the same extent of phosphorus in a basic-lined furnace, and cannot be said at all when speaking of the action of phosphorus upon iron in acid-lined furnaces.

The above statement is illustrated by the fact that good tough cake may (and probably ought to) contain .5 per cent. of arsenic.

The author knows of no steel or wrought iron that is of any commercial use at all that contains anything like this percentage of phosphorus.

The author would remark, finally, that the results that he gives this evening are to be considered merely as sufficient to encourage copper smelters to obtain infinitely better results.

In conclusion, the author wishes to place upon record his indebtedness to the various companies as represented by their directors and officials who have with so much enterprise and skill employed the basic process in the manufacture of copper. To a former assistant of his, Mr. Joseph Cooper of Middlesbro', he is also indebted for his untiring zeal and for the great ability that he showed when superintending the putting in of the first basic lining to a coal-fired copper roaster, and when superintending the working of this and other similar furnaces. To his valued assistant and friend, Mr. Thomas Twynam, he is also deeply indebted for supervising the working of the basic roasters and refinery furnaces, and for the valuable assistance that he has rendered in the compilation of this paper.

DISCUSSION.

The CHAIRMAN complimented the Section on having the paper brought before it, and considered that the author had fully made out his case, viz., the superiority of a basic lining in the refining of copper.

Prof. W. C. ROBERTS-AUSTEN said that it was very difficult for those who were not actually engaged in copper smelting to realise how bitter an enemy to the smelter small quantities of impurity could really be, and it was still more difficult, perhaps, for those who had not made the relations of "traces" of impurity to masses of metal a special study to understand how important, and at the same time how hard it was, to get rid of small traces of impurities. Speaking from the point of view of the Mint, he might observe that even so small a quantity as one-tenth per cent. of bismuth in copper would render it impossible to use that copper for coinage purposes when added to gold. Arsenic was not quite so bad; but a very small proportion of it would in the same way render copper wholly unfit for coinage purposes when added to gold. Again, arsenic exerted a remarkable influence in increasing the electrical resistance of copper, and it was well known that the copper used for the electric wires of the present day would carry double the number of messages that could be carried by the old wires made in the days when the necessity for the purification of the copper was not so well understood. That alone showed the great importance of eliminating the impurities. But with the old acid-lined furnaces it was extremely difficult to get rid of the arsenic without basic additions to the charge or without much loss of copper, and it was also difficult to dissociate by heat the arsenical compounds which were formed. He would like to ask the author whether he thought that, in the case of the Manhès process (where the acid lining of the converter played so important a part in the reactions), the substitution of a basic lining at any stage of the process would afford anything like the service which it had been shown to render in the metallurgy of iron. Mr. Gilchrist had incidentally referred to the belief that the "nature," or what should be called the molecular structure of the metal, was of much importance in the case of both iron and copper. Prof. Austen regarded the molecular grouping of a metal as being of the greatest importance. It had been proved in the case of iron that there was an α and a β form of the metal, each with distinct properties of its own. He believed that it would be found that copper was in a similar case, and that a very minute quantity of foreign matter might be able to change the normal form into the allotropic. He had had very little actual experience of copper smelting, but he fully appreciated its difficulties, and it was most unusual for anyone who, like Mr. Gilchrist, had won his laurels in connexion with one particular metal, to come forward again and distinguish himself in connexion with another and very different metal.

Mr. DAVID HOWARD inquired whether the furnaces with the basic lining were worked in all respects the same as with the acid lining, or whether a different flux was used in each case.

Dr. B. MOUR said he did not think that the converter so far had been successful for copper smelting. When used for concentrating copper ores or matte, by slagging off the iron in form of a silicate, the large amount of slag so formed greatly interfered with the operation. When treating white metal or blister copper in an acid-lined converter with the view of removing arsenic and other impurities, the rapid oxidation of the copper under a high pressure blast would cause an excessive quantity of copper to be converted into silicate or slag. Here better results might be expected from a basic-lined converter. The removal of arsenic, however, had been successfully carried out in a basic-lined reverberatory furnace which had the advantage of being much simpler and more economical in its working.

Mr. BERTRAM BLOUNT said that as an analyst he was accustomed to see specifications, drawn by engineers experienced in copper, for such things as locomotive firebox plates, and in such specifications different percentages of impurities were put down as the maximum limit to be permitted. A very common maximum for arsenic was 0.15 per cent. The engineers who drew those specifications—and, presumably, their chemical advisers also—had arrived at the opinion that that percentage was the maximum allowable; but their reasons for doing so were not evident. He knew that work had been done in the past on the determination of arsenic and other impurities in copper; but it was difficult to find anything like an adequate account of the possible ill effects of that body on the metal. Would Mr. Gilchrist be inclined to fix for refined copper, such as was used for firebox plates, a definite maximum of impurities which should not be exceeded, and would he as an analyst condemn without hope of appeal copper which exceeded that limit? Also would he consider that such limit might be altered by the contemporaneous presence of other impurities in the copper? Until some such information were available, analysts could, it was true, determine the precise percentage of arsenic and similar impurities, but were unable definitely to advise their clients when that percentage so far exceeded the maximum permissible as to unequivocally condemn the copper.

Mr. W. GOWLAND regarded the paper as one of the most valuable contributions to the literature of the subject published since Dr. Percy's great work. Mr. Gilchrist's results might be accepted as correct; and, as far as works were concerned, the process was likely to be successful on a commercial scale.

Dr. W. S. SQUIRE said that he had been attracted to the meeting by curiosity excited by the title of the paper. His curiosity was aroused by the fact that the process of copper smelting was well known to be an acid process from beginning to end. As the members were no doubt aware, the object of smelting copper was, first, to convert the sulphides of iron into oxide, and dissolve them out by means of silica as a slag. Having got rid of a certain quantity of the iron in that way, the ore was roasted again, and again smelted with silica, and so became richer in copper. In fact, silicic acid was used just as hydrochloric acid was used in other processes, to dissolve out impurities. Yet he gathered that the basic process might be applied to refining copper. He joined Professor Roberts-Austen in congratulating Mr. Gilchrist on having dealt successfully with two different metals, and both by the basic process. But it appeared to him that just as the basic process was applied not to the smelting of iron but rather to its refining, in the process of making steel, so in the present case it was applied to the refining of copper, and not to its smelting, the arsenic being removed from the copper much in the same way that the phosphorus was eliminated in the steel process.

Mr. J. SMITH, who said that he had come from St. Helens expressly to hear Mr. Gilchrist read his paper, wished to express his sympathy with the gentleman who had spoken about engineers tying copper producers down in their specifications to certain percentages of impurities. They had as a rule to give guarantees that their product should consist

of 99.5 of copper and .5 of impurities, and of that .5 not more than .15 should be arsenic. The remaining 3.5 might be anything they liked. There was no doubt in his mind about the .15, for during close on the 28 years he had been engaged in the copper trade it was a subject that had given them an immense amount of trouble, and they had more trouble now than formerly in guaranteeing the tests required by engineers. Would Mr. Gilchrist recommend the production of metallic bottoms and their treatment in the basic roaster as the best way of treating arsenical precipitates? The treatment of those precipitates had become an important question for copper smelters. Last year they had to deal with them up to 2 and 3 per cent. of arsenic, and at the present time up to something like 5 per cent. They were expecting a great deal of trouble with the precipitates in the current year, as there would be almost double the quantity of arsenic to be got rid of. He would therefore be grateful for any hints as to the best way of dealing with that extra quantity.

Mr. E. RILEY did not know upon what grounds engineers based their requirement that copper should contain not less than 99.5 of pure metal; it was a very high limit to fix. There was always oxide of copper present, and the whole question of the limit of allowable impurities might well form a subject of discussion between chemists and engineers. In his own practice he made a point of giving no figures. He certified that the materials were, in his opinion, fit for certain purposes. If he gave an analysis it might be a specially good analysis, and then the probability was that his clients would want more material exactly like that certified. That would be most unfair to the manufacturer. In the case of iron he simply certified that it was fit for the Bessemer or Siemens process, and in the case of steel, that it was of good quality, and fit for its purpose. At the same time, he of course entered in his own books the figures of the analysis. He thought that the same plan should be adopted with regard to copper. Anyone who had had a long experience of metals was better able to judge what their chemical composition should be, and whether they were suitable for a given purpose, than an engineer who had perhaps only a little experience of them. Engineers should, he thought, confine themselves to the mechanical tests. It would be a subject well worthy of examination to fix the actual amount of pure copper in good commercial copper. He had made many experiments himself, and he fixed it at 99½. He thought that 99½ was decidedly too high.

Mr. T. GRUB had been much interested in this paper, having, for years, smelted copper by basic methods, though not on basic bottoms. For the paper, as a whole, he had nothing but approval. The lines on which Mr. Gilchrist had gone were right, and the principles on which he had done so much in steel had given such results in copper as one would have expected from his own experience in smelting basic charges. The smelting on acid bottoms, of which details were given for comparison with the basic process (see pp. 5, 6, 7, 8) must, at this day, be considered very bad. With modern skill in smelting not only should there never be such a result as 191 tons of blister from 400 tons of bottoms, but in each example of smelting on acid bottoms, given on the pages cited, the quantity smelted, in the time, should not have been much less than double, whilst a much smaller proportion of copper should have been slagged. It did not appear from the paper, but would be, of course, known to all present, that the copper slagged was not lost, and that the oxide of copper in those slags played an important part in bringing sulphides forward to metallic copper in the usual operations of copper smelting. Referring to remarks by previous speakers, with regard to engineers' specifications, he thought a want of knowledge of the chemistry of copper was apparent when smelters were tied down to .15 per cent. of arsenic in locomotive fireboxes. For this and most uses of tough-cake copper it might contain nearly 1 per cent., and be all the better for it. It had been fully proved that fireboxes containing ½ per cent., and more, of arsenic, were much better than those of pure copper. In fact, for every purpose for which copper was used in sheet or wire, except electrical conductivity, it was

all the better for $\frac{1}{2}$ per cent. of arsenic, and the greater part of the tough-cake copper now made contained that proportion or more. Best select copper rarely contained more than .05 of arsenic, and very much contained only .02. He might say to Mr. Riley that they did not miss the arsenic in their analyses. If it was there, even in the third decimal place, it was accurately estimated. With regard to the elimination of arsenic from precipitates, Mr. Smith need have no doubts or fears on that point. All he had to do to overcome the difficulty of increasing quantities was to follow the lines laid down by Mr. Gilchrist or work with basic mixtures. That would enable him to make satisfactory tough copper, although for B.S. copper he would do well to smelt for copper bottoms rather than rely on oxidation only.

Mr. GILCHRIST, referring to Mr. Gibb's remarks on the results shown on page 5, inquired what Mr. Gibb would consider a fair average yield from an acid furnace in lieu of those results, bearing in mind that they started with 6 per cent. of arsenic.

Mr. GIBB replied that from 400 tons of copper bottoms he should expect at least 250 tons of blister, and a considerably larger yield than this could be attained on acid bottoms. Even beginning with such material as Mr. Gilchrist had referred to, no such large proportions of 55 per cent. slag, as that given, should ever be approached.

Mr. E. RILEY, referring to Mr. Gibb's statement that certain coppers might contain as much as 1 per cent. of arsenic and he all the better for it, wished to ask that gentleman whether, under such circumstances, the other elements contained in the copper ought not to be taken into account. It was well known that a steel containing .12 per cent. of phosphorus and .15 per cent. of carbon would stand all the mechanical tests for axle steel. But if one put in a steel containing nine-tenths per cent. of carbon and only .04 of phosphorus and made it into bullets, the bullets would all go to pieces. In fact the amount of phosphorus one might have in steel depended upon the amount of carbon present. If the carbon were low, the phosphorus might be high, and *vice versa*. He would suggest to Mr. Gibb that some such rule might apply to copper, and that therefore all its constituents ought to be taken into account.

Mr. CLAUDE VAUTIN said that, having spent a considerable portion of his life in the copper works of Cobari in Australia, where they were greatly troubled with bismuth in their refined copper, he had hoped that Mr. Gilchrist would have been successful in eliminating bismuth as well as arsenic. He found, however, that the bismuth had given him as much trouble as it had other investigators. It was during some of the experiments with the Cobari copper that the metallic bottoms were fused with basic material, the result being that the arsenic had been reduced fully 50 per cent., but the bismuth practically remained the same after as before treatment. As to the effect of basic lining in converters for Bessemerising copper, he had worked at this for over two years at Cobari, and the result was a larger output of copper with a less percentage of slag than when using acid-lined converters. The Bessemerising of copper mattes was abandoned on the score of cost. It still remained a problem how to successfully remove bismuth from copper during the ordinary smelting operations.

Mr. A. G. PHILLIPS said that the process struck him as being one for obtaining more copper and less slag from a given quantity of bottoms, rather than a method of copper purification. For example, on page 6 an analysis of the metal charged into a basic and an acid furnace respectively showed 0.47 and 0.51 per cent. of arsenic, and the blister copper turned out by the basic furnace contained 0.59 and that from the acid furnace 0.58 per cent. Again, on page 9, he saw that a copper precipitate containing 0.15 turned out 0.068 of arsenic in the refined copper, and on page 10 a charge of blister containing 0.77 of arsenic turned out a tough cake containing 0.71. Those results could be easily attained in an acid furnace, and therefore the process was essentially one for obtaining more copper and less slag rather than for purifying copper. If so, the whole question

became one of cost, and would depend upon whether the extra copper obtained was sufficient to pay for the greater expense—if it were greater—of the basic lining. But as far as purification went, the process did not seem to have anything like the same effect as in the treatment of iron, in which case practically the whole of the phosphorus was removed with the slag.

Mr. PERCY GILCHRIST, in his reply, said: Professor Roberts-Austen had asked him whether he thought that the basic lining would render the same amount of service in the Manhès process of Bessemerising copper that it had in the reverberatory furnace. On that point he quite agreed with the gentleman from Australia, and would say that if one applied the basic lining to a converter, one would get a greater yield of copper and less slag than when using an acid lining. But he did not believe in applying any system of Bessemerising to copper at all. Copper was for all practical purposes 40l. a ton, and therefore the question of yield was of great importance, and time and labour minor points. In his opinion it would be impossible to pick up as completely as if they had never fallen the projections that must be thrown out in any system of Bessemerising, and therefore there must be greater waste. To take another point of view: In the case of steel making, we were gradually coming to produce steel in the open hearth furnace as cheaply as it could be produced in the Bessemer. One of the greatest engineers of our century (the late Alex. Holley) said some 10 years ago that he was of opinion that the open-hearth furnace would eventually attain results as good as the Bessemer. He (the speaker) did not know whether that would ever be the case in acid steel making, but he certainly thought that it would be so in the case of the basic process. If that were so in the case of steel, still more likely was it to happen in the case of copper. He was not one of those who thought that the copper manufacturer needed no improvements. No metallurgy that he knew of needed so much improvement as that of copper. The copper manufacturer wanted not only people who could make analyses, but people who could tell him how to use the analyses when made. There was one improvement obvious to all, and which had already been made by a gentleman present, who was rather ahead of some of those in the trade, as he had applied gas-producers to copper smelting, *i.e.*, using gas instead of the good old wasteful fire-grate of South Wales. He did not say that it was necessary to use regenerative chambers. He doubted if it was. But he thought if gas-producers were used instead of the old fire-grates they would be able to defy any system of Bessemerising.

Mr. Howard had asked whether the basic furnaces were worked in all respects as with an acid lining, or whether different fluxes were employed. The acid-lined furnaces, when they were used to treat arsenical materials, had some very small percentage of slaked lime added to the charge. When a basic lining was employed, there was used, he thought, as many hundredweights of lime as there were pounds used in an acid-lined furnace. But in all other respects, bearing in mind that lime was used for stopping the tapping-hole, the working was the same. The quantity of sand required for fettling an acid-lined furnace, if taken by weight, would, he thought, surprise some principals, if not their managers. When one had seen a thing done every day of one's life, one got used to it, but if one came fresh to the matter and weighed up the sand used in treating blister copper, it would make one reflect a little.

He had been asked whether he would be inclined to fix any limit for arsenic in copper. Their great master, Dr. Percy, always impressed on his students that analysis would teach nothing unless one started by analysing either a success or a failure. In other words, if one had something that answered either well or badly, they knew what to do. But unless they could so work, analysis was of no use at all. There were copper works which had for many years employed a considerable staff of analysts, and had got into the way of using their results, and they knew very well what percentage of arsenic suited for a particular purpose. It was perfectly well known that if one had, say, 1 per cent. of carbon and as little manganese as possible in a sample

of steel, that was a good razor steel, while if one had fifteen hundredths per cent. of carbon and low manganese, that would be a good boiler plate steel. And so with copper. The proportion of arsenic that would suit very well for tough cake purposes would not do at all for electrical purposes, and so on. The suppliers of the material should, and the best of them did, analyse both their successes and their failures, and when a man required copper for a particular job, he had only to repose confidence in the copper maker and he would be well served. If he did not place that amount of confidence in the maker he did not deserve to be well served.

He was much indebted to Mr. Smith for the compliment he had paid him in coming so far to attend that meeting. In reply to both his questions, he would say emphatically, Yes! He was willing to stand or fall by the results given in the paper, and he was sure they would bear out what he said, viz., that the best way of treating arsenical or impure ores was to produce metallic bottoms in a basic-lined furnace. And he would recommend a basic roaster for treating white metal, a basic roaster for making bottoms into blister, and a basic refiner for refining the blister, whether into B.S. or a quality beyond B.S.

He would now reply to the last speaker (Mr. Phillips), who thought that, because he found in some results 0.7 of arsenic, and so on, they could not get lower. He would refer him to a few of the other analyses, but before doing so he would remind him that there was an old saying, that one should not throw pearls before people who did not appreciate them. He would point out to him that copper was worth 40*l.* a ton, and arsenic, as found in tough cake, nothing. It seemed to him a very elementary commercial principle that if one could get 40*l.* a ton for the arsenic with the copper, it would be very foolish not to leave it in, provided the copper would suit the job it was required for. In that particular case they did not want anything purer. But if he would look at page 11, amongst other places, he would see that 1.93 of arsenic had been reduced to .062, and that 1.52 had been reduced to .05. And there was one other case in which Mr. Riley had reported that the arsenic was reduced to nil. Mr. Riley had told them that he never failed to find arsenic when there was arsenic to find. He (the speaker) had his certificate, and he had no doubt that it was correct. But whether it was nil or .01, the point he wished to make clear was this: that if one wanted .02 or .07 per cent., one could get it if one started with blister containing 1.5 to 2.0 per cent., and if one wanted a mere trace, one could get it when starting with blister containing $\frac{1}{2}$ per cent. of arsenic.

Dr. Squire had attacked the title of the paper, and, the author thought, quite rightly. But one had to be terse sometimes; for instance, to talk of basic steel was unscientific. At the same time, it conveyed the meaning one wished to convey. With respect to the basic process as applied to copper smelting, he did not think that one could call a roaster a refiner; but if any gentleman could suggest a better word than that which he had used, and the rules of the Society allowed of it, he would be happy to adopt that word.

Mr. Gibb had, he thought, acted very fairly as the spokesman of a good many smelters, who said that the 191 tons shown on page 5 was a bad yield for an acid furnace. There was just one question he would like to ask him and his friends. He did not want them to tell him what they thought their yield would be when they treated bottoms containing 6 per cent. arsenic, but what it *had* been under similar circumstances. That would be interesting, and would show whether the 191 tons was really too low. Whatever their figure might be, he thought it would allow the basic process some gain. But with regard to the percentage of arsenic, given at 6 per cent., he thought he could show—and it might increase the interest of the paper if he did so—that 6 per cent. of arsenic was a low average. If there were any errors of that kind in the paper, they were due to the fact that, being lazy, he had found it easier to understate his facts rather than take the trouble to state them exactly, as he should have done. In many cases "metallic bottoms" contained as much as 9 per cent. of arsenic, and he would remind them that to sample bottoms was by no means an easy job. The analysis of them was

bad enough, but the sampling was worse. If any error had been made, it was on the lower side and not on the higher. He would also remind them that every $\frac{1}{2}$ per cent. extra of arsenic to be got rid of enormously increased the waste, so that if 6 per cent. of As was sometimes 7, 8, and 9 per cent. arsenic, the waste would then enormously increase, especially in an acid-lined furnace. He was sure that Mr. Smith and other practical men would corroborate him in that.

He thought that he had now dealt with all the questions put. If he had not, however, and the rules of the Society permitted it, he would be happy to reply to any further queries which members might wish to put after reading the paper. As he had said in the paper, he regarded the statements and results given therein as merely the starting point. He looked to those practical men who spent their lives in making copper to develop the method, and if they did, he predicted that they would, when using a basic lining, be able to get any result they desired.

MR. A. NORMAN TATE IN THE CHAIR.

AN APPARATUS FOR THE DEVELOPMENT OF PHOTOGRAPHIC PLATES WITHOUT THE USE OF A DARK ROOM.

BY ALEXANDER WATT, F.L.C., F.C.S.

THE apparatus which I bring before you to-night was in use for two months before I learned that a "portable developing box" similar to it in many respects, had been described by Dr. T. W. Harvey in the International Annual of Anthony's Photographic Bulletin for 1888. But as the apparatus about to be described differs from it in principle, and is based on the photochemical investigations of Messrs. Hurter and Driffield, I have thought that this communication might be of interest to the Society.

In the paper which we had the pleasure of listening to last session (this Journal, IX., 455—469), Messrs. Hurter and Driffield have shown that of all the conditions involved in the production of a "perfect negative," those relating to the exposure are by far the most important, and if the exposure factors are so adjusted as to give the "correct exposure," the development is of secondary importance, as the density gradations of the negative are entirely due to the action of the light.

It therefore occurred to me that with a correctly exposed plate, development might be carried on quite mechanically, as the required density can be regulated by the length of time of development.

On trying the experiment of allowing plates which had been exposed by the aid of Hurter and Driffield's actinograph, to remain in the ferrous oxalate developer for different lengths of time, it was found that with the same quality of plate satisfactory negatives could be obtained in 10 minutes with a strong solution, and in 15 minutes when the solution was diluted with an equal volume of water. When the time required to obtain a suitable printing density had been ascertained for a particular plate, it was found that there was nothing gained by watching the progress of the development, and consequently the dark room might be dispensed with if means could be found to keep the plate in the dark during development and in its transference from the dark slide to the developing vessel.

In order to attain this object I have devised the apparatus which I have named a dark developing bath.

It consists of a metallic case, A (Fig. 1), only slightly larger than the plate for which it is intended, which can be closed light-tight by means of the lid B. It is furnished with two tubes, one, C, entering at the bottom of the bath, which can be connected by a piece of india-rubber tubing, E, to the funnel D; the other is near the top, just above the level of the plate P. The former serves to introduce the developer into the bath, and the latter, F, allows the air to escape and also acts as an overflow.

Fig. 1.

Fig. 3.

The funnel D and the india-rubber tube E are supported by means of the hooks K K, which fit into the eye L. The tubes are so bent that no light can enter the bath. An end view of the bath is shown in Fig. 2, in which a moveable hook, I, fitting into the socket J, serves to fix the bath to any convenient support.

A section, Fig. 3, shows the plate P, the film side of which is kept from contact with the side of the bath by means of the metallic strips H.

When the bath is intended for the development of films or paper prints, it is furnished with a carrier (Fig. 4) into which the film or paper is inserted before being put into the bath, and when required for the development of several plates at one time, it is constructed with grooves as in an ordinary plate box.

The bath is used as follows:—The dark slide containing the exposed plate and the bath are placed in a changing bag, into which it is only necessary to insert the hands. The plate is then transferred from the slide to the bath, care being taken to keep the film side towards the back of the bath.

After being closed, the bath is withdrawn from the bag into daylight, and fixed vertically to any convenient support

by means of the hook. A vessel is placed under the overflow tube, and the inlet tube is attached to the funnel, which after being filled with the developing solution, is raised and lowered several times, to alternately fill and empty the bath, and so ensure the removal of air-bells from the surface of the plate. After standing sufficient time to complete the development, the solution is run off from the bath. The plate is washed by running water through the bath (either by means of the funnel or by attaching the india-rubber tube direct to a water tap), after which it is taken out, in daylight, and "fixed" in a covered tray.

If it be desired to "fix" entirely in the dark, the operation may be conducted in the same bath or in a similar one to which the plate has been transferred in the changing bag.

The final washing of plate may be done either in the bath or in the usual way.

The best developer for use with the dark bath is ferrous oxalate, on account of its property of not producing "fog," even when a plate has been left in it for an hour (Hurter and Driffield, loc. cit. p. 459). It should be made just before use from the following solutions prepared according to Thomas's formulae—

No. 1.

Potassium oxalate.....	300 grms.
Potassium bromide.....	2'2 "
Water to make.....	1,000 cc.

No. 2.

Ferrous sulphate.....	400 grms.
Sulphuric acid.....	3 cc.
Water to make.....	1,000 cc.

To four parts of No. 1 add one part No. 2, and water to make eight parts.

When the developer is used at once with Thomas's "Extra Rapid" plates, from 12 to 15 minutes in the bath at about 15° C. is sufficient to give a satisfactory negative, if the exposure has been correct.

The time required to obtain a suitable density is found by placing the exposed plate in the bath and adding the amount of developer required to fill the bath, in four equal portions at intervals of five minutes. Four densities are thus obtained by developing for 5, 10, 15, and 20 minutes respectively, from which observations the time that gives the desired density is selected.

A very small bath to contain four plates (a $\frac{1}{4}$ -plate cut into four) is useful for the development of test plates exposed in the camera on a landscape in order to ascertain the speed of the plate, as recommended by Mr. V. C. Driffield (Photographic Soc. Reporter, April 1889).

A developing bath constructed as above, besides enabling plates to be developed *without a dark room*, has some other advantages over the ordinary developing tray. The bath being used vertically presents a very small surface of liquid to the air, thereby preventing the rapid oxidation of the developer. As the solution is introduced at the bottom, under pressure, it flows up evenly over the plate, carrying the air before it and so prevents air-bells. The plate is completely immersed in the solution during development. The bath being quite light-tight, there is no risk of "fog" from access of light to the plate, and is therefore especially suitable for the development of isochromatic and other very sensitive plates. The tubes attached enable the solution to be readily run off and replaced by one of altered composition, and also allow of a continuous flow of developer through it.

As this apparatus has been designed for the development of correctly exposed plates, any plates developed in it which are either over- or under-exposed will be more or less defective. If, however, the exposure has been nearly correct a passable negative will be obtained, but if it has been *widely different* from the correct one, as no provision is made for remedying the defect, the negative will be a failure, but if such a result should lead to more attention being paid to the exposure it will not be altogether to be regretted.

REVERSAL AND SECOND NEGATIVE.

BY H. J. L. RAWLINS.

IN their paper, read before this Society in May last (this Journal, 1890, 456 seq.) Hurter and Driffield showed, by means of a diagram, a curve representing the action of light on a sensitised plate, the action producing, on development, increasing density as its duration was continued up to a certain point, after which a further action of light caused reversal to commence, and the density diminished. The following experiments were undertaken in order to ascertain whether, and at what point, this decrease of density ceased and gave place to a second increase.

An Ilford ordinary plate was exposed to direct sunlight in 15 sections, the first for a second or two, in order to thoroughly fog it, the second for one minute, and the remaining sections for 2, 4, 8, 16, 32 minutes, and so on, up to the last, which received 8,192 minutes exposure. The plate was then developed with a weak quinol (hydroquinone) developer, when the following result was obtained:—Section 1 showed clearly the usual action of light on a plate. In section 2 (one minute exposure) reversal had already commenced, and was clearly seen in all the sections up to that which had received 128 minutes' exposure, where it was very complete. After this point density again increased, and in the section that had received 8,192 minutes' exposure it was very considerable.

With a view to finding out whether, beyond this point, a diminution of density set in, a second (Ilford ordinary) plate was exposed in four sections, the first for one or two seconds, the second for 128 minutes (the point of most complete reversal in the first experiment), the third for 8,192 minutes, and the fourth for 16,384 minutes. The plate was then developed as before, and the following result was obtained:—Section 1 showed the density of, say, a rather weak sky in a landscape negative. Section 2 was practically clear glass. Section 3 was about equal in density to section 1; and section 4 had nearly double the density of section 3.

Reasoning from these experiments, and assuming that the curve representing increasing and decreasing density would continue to be formed as it was up to the point of 16,384 minutes exposure, a diagram was prepared, in order to ascertain the length of exposure required to obtain a second period of reversal. Of course, such a diagram was of necessity largely approximate, as it was quite impossible to keep an accurate record of the intensity of the light acting during the experiments; but it appears at least probable that the condition of second reversal would not be produced until direct sunlight had acted upon the plate for something like seven years. An experiment to prove this was, however, not undertaken.

GREASE-SPOT PHOTOMETER MEASURES.

BY CAPTAIN ARNEY, C.B., D.C.L., F.R.S.

AS I may not be able to be present at the meeting of the Liverpool Section of the Society of Chemical Industry, on December 3rd, I have thought that I might in some way add to the interest of the papers which I understand Messrs. Hurter and Driffield are to read on that evening. I have already appeared in the Journal of the Society as a critic of their former paper, but I have one or two new points to bring out as regards my own photometer and that which they use, as, owing to their kindness, I have been temporarily put in possession of some negatives which they have measured, and of which I have also recently determined the transparency.

In the first paper read by these authors there was a blow aimed at the sector photometer which, in my subsequent communication, I thought I had successfully parried. Messrs. Hurter and Driffield, however, have continued to make the allegation of incorrectness against it, but have so far given no experimental proofs to warrant their assertion, and this I challenge them to do, by experiments made by direct measures of naked light which do not involve the measurement of the density of negatives.

In their paper we had a statement that the semi-shadows which the sectors must of necessity cast upon a screen when a source of light like a lamp is used, vitiated the results, and that there was a mathematical proof of the fact, which up till now has not been forthcoming, though it possibly may be in the paper about to be read. Such a proof would be very interesting, but I expect would contain some fallacy if Dr. Hurter's own admission be conceded as correct. The following line of argument may recommend itself to the meeting, though it contains no mathematical formula:—In a letter to me, which I hope Dr. Hurter will not think I ought not to quote, he states that the sector photometer is right theoretically when the source is a point of light; and on this one admission it is not hard to build up the truth of its correctness for a source of light of any practical dimensions. If we take as a source an argand burner, we may consider it made up of a large number of small points of light of very small dimensions. Could we isolate one of these points, the illumination of a screen would be diminished exactly proportionally to the apertures of the sectors rotating between it and the screen. (This Dr. Hurter admits.) Another point would do the same, and so on as each one was isolated. If this be true for each individually, the same is true for these all collectively. Hence, the proposition seems very fairly proved, on the admission made, and that the size of the source of light has nothing to do with the correctness of the measures, and the question of what is called the semi-shadow, which must naturally exist, vanishes.

Most people, however, prefer practical experiment to theory, and I now propose to put before the meeting the results of measurements obtained by the sector photometer, the ordinary Rumford photometer, and the grease-spot photometer, the last measures not made by myself, but by Messrs. Hurter and Driffield themselves, so that in them there is no bias in the readings. In my criticism of these gentlemen's paper, my contention was that from experiments made and from theoretical considerations, which I tried to fully explain, as to the scattering of light by the silver particles, the measurements made by them of the light passing through a negative were too small, and consequently that the density of deposit they arrived at was too great, and this I believe the subsequent experiments will amply prove. But besides this, they will prove practically that the sector photometer at all events contains no elements of the error, though it was scarcely necessary to show this again after the results which I gave in my criticism.

The method of measuring densities, which I consider to be devoid of all error, except those inherent to the eye, I have recently discussed at the Camera Club, and I will briefly recapitulate it. If a square of about half an inch size be cut in an opaque plate, such as a ferrotype plate, and the whole covered over with white paper of the consistency of Saxe paper, and an oblong of black paper, one inch by half an inch, be pasted over the white paper, so that half the aperture is over the hole and the other half over the opaque white surface, we have two white squares side by side, one translucent and the other opaque to transmitted light. We can place behind such a screen a light, and the translucent space will be bright whilst the other will be dark.

If we place another light in front of the screen both the squares will be illuminated by reflected light; but by placing a rod between this front light and the screen we can cause a shadow to be cast, so that only the opaque white square is illuminated by the front light. We can now make both squares equally bright, either by placing rotating sectors between the light and the rod, and altering the apertures, or else by shifting the light nearer or further from the screen. The light which illuminates the translucent square is best kept as the stationary light, as then any reflected light which might chance be in the room will not vitiate the results. Reflected light on the front side of the screen is of no moment, as it equally illuminates both squares. As a matter of precaution care has been taken to prevent any light except that from the two sources reaching the screen. Now, if a piece of a negative be placed in contact with the aperture in the screen so that the back light shines through

it on to the white paper, evidently all the light which can pass through the negative will reach the paper which is not the case, as can easily be tried if it be removed away from the screen (as it practically is in Hurter and Driffield's photometer). The brightness of the illumination of the translucent square can again be equalled on the other white square by the front light, by means of the rotating sectors, or by moving that light away from the screen. Both these plans were used by me for measuring the light transmitted through three different negatives, marked and measured by Messrs. Hurter and Driffield, as No. 1, No. 2, and No. 3, which are stated in a table which accompanies them, to be made by cutting a plate into three portions, after exposing different slips for 10, 20, 40, and 80 seconds to light, so that each negative contains the same four exposures. The development of each negative was different, however, No. 1 being carried on for 2 minutes, No. 2 for 4 minutes, and No. 3 for 6 minutes in the same developer. The densities derived from these measures were marked by them on the negatives, and correspond with those given in the tables. My results are given in the following tables, but I believe the sector photometer readings are slightly the better of the two.

These measures of No. 1 negative I will give in detail from my note-book—

Phot. Measured.	Aperture Readings.	Mean Reading.	Light Transmitted.	Density	A's Density less Fog.	H. and D.'s Density
Naked light	81, 81, 79½, 79, 80.	80	1.000	0
Fog on plate	72, 72, 72	72	.900	.046
10 sec.	45, 46, 46, 46, 45, 46.	45.7	.571	.243	.197	.235
20 sec.	30, 32, 31, 32, 32.	31.4	.392	.406	.360	.445
40 sec.	22, 22, 22, 22.	22.0	.275	.560	.514	.680
80 sec.	14½, 13½, 14, 14, 14.	14.0	.175	.700	.715	.920

MEASURES BY MOVING LAMP FROM THE SCREEN.

Phot. Measured.	Distance of Lamp from Screen.	Mean Reading.	Light Transmitted.	Density	Density less Fog.	H. and D.'s Density
Naked light.	21.3, 21, 20.7, 20.7, 21.3.	21	1.000	0
Fog..	22, 22, 21.8, 22.3	22	.911	.041
10 sec.	27.8, 27.8, 27.8	27.8	.570	.244	.203	.235
20 sec.	33.2, 33.1, 33.8, 33.3.	33.4	.389	.410	.360	.445
40 sec.	40.1, 40.3, 40.3	40.2	.273	.503	.522	.680
80 sec.	49, 50, 51, 50	50	.176	.754	.713	.920

In all three negatives Hurter and Driffield's measure of the fog was .110.

Another independent measure made with the sectors gave the densities :—

Photo. Measured.	Densities.	Density less Fog.
Naked light.....	0	..
Fog.....	.043	..
10 sec.243	.200
20 sec.399	.356
40 sec.557	.514
80 sec.756	.713

No. 2.

SECTORS MEASURE.

Phot. Measured.	Mean Reading of Aperture.	Light Transmitted.	Density.	Density less Fog.	H. & D.'s Density less Fog.
Naked light..	80	1.000	0
Fog.....	72.6	.907	.043
10 sec.	33.3	.416	.381	.338	.410
20 sec.	19*	.237	.626	.583	.740
40 sec.	9.6	.120	.921	.878	1.085
80 sec.	4.75	.059	1.229	1.186	1.490

Hurter and Driffield's measure of the fog, .110.

MEASURES BY MOVING THE LAMP FROM THE SCREEN.

Phot. Measured.	Mean Reading of Distances.	Light Transmitted.	Density.	Density less Fog.	H. & D.'s Density less Fog.
Naked light..	21	1.000	0
Fog.....	22	.911	.041
10 sec.	32.5	.418	.378	.337	.410
20 sec.	43.5	.233	.633	.592	.740
40 sec.	60	.122	.915	.873	1.085
80 sec.	87	.057	1.244	1.203	1.490

No. 3.

SECTOR MEASURES.

Phot. Measured.	Mean of Readings of Aperture.	Light transmitted.	Density.	Density less Fog.	H. & D.'s Density.
Naked light..	80	1.000	0
Fog.....	72	.900	.045	0	..
10 sec.	28.4	.355	.450	.405	.470
20 sec.	14.0*	.175	.777	.732	.865
40 sec.	6.28*	.1078	1.108	1.063	1.335
80 sec.	2.51*	.031	1.509	1.464	1.800

Hurter and Driffield's measure of the density of the fog was .110.

MEASURES BY MOVING THE LIGHT.

Phot. Measured.	Mean Distance.	Light transmitted.	Density.	Density less Fog.	H. & D.'s Density.
Naked light..	14	1.000	0
Fog.....	14.8	.900	.045
10 sec.	24	.338	.471	.426	.470
20 sec.	33.7	.172	.765	.720	.865
40 sec.	51.0	.076	1.119	1.074	1.335
80 sec.	81.0	.030	1.523	1.478	1.800

The numbers marked * were obtained by moving the back lamp closer to the screen and obtaining higher readings, which were reduced by a factor. The first readings gave the same within the limits of error of reading the sector scale.

Now a look at these tables will show two things: First, that the readings by sector photometry and the ordinary shadow photometry are in reality the same, and any difference is due to error of observations; and secondly, that in every case the densities obtained by these measures are *invariably much smaller* than those obtained by Messrs. Hurter and Driffield with the grease-spot photometer; even the fog of the negative they show has more than double the density that I obtained. Now there is one thing perfectly evident, that whatever influence a negative placed in the path of the beam can have as regards the readings obtained, say with the Rumford method, it can never make them show that the light which appears to be transmitted is *greater* than it is in reality, though it would easily make it appear to be less owing to the scattering of light. It is to be presumed, therefore, that the smaller measures are nearer the truth than the larger, and I do not hesitate to say that the values obtained by my measures are correct within the limits of the error of observation.

I quite expect to be told that the method of using the screen is wrong; I am not merely going to assert it is right, but will give a reasonable proof of its correctness, though I would have you remark that, as the two sets of measures were obtained under the same conditions, even were the screen wrong, the comparison between the sector and Rumford methods would still hold. If we have a fixed light which is sufficiently intense to print through the negatives on to platinum paper, we can then arrange to compare the density of one part of one negative with that of another part of another negative by placing these negatives at proper distances from the source of light and comparing the blackness produced under each part. Now, acting on these lines and knowing that from the colour of the negatives (they were probably developed by ferrous oxalate, as the authors say they always use that developer) the photographic and optical densities were very nearly alike, a comparison was made between the *smallest* (the fog) density on No. 1 and the *greatest* density on No. 3. Messrs. Hurter and Driffield measured the difference of these densities as 1.800,* which is equivalent to saying that the light transmitted by the latter was $\frac{1}{63.2}$ that of the former.

My measures gave the difference in density as 1.464, or $\frac{1}{20.1}$ of light was transmitted, a difference of over 100 per cent. If we wish to test Messrs. Hurter and Driffield's measures of fog density on No. 1, and of the greatest density on No. 3, we ought to place No. 1 negative $\sqrt[4]{63.21}$ or 7.95 times further from the light than No. 3 negative, and then the blackness produced on the platinum paper, with the same exposure under the fog part of No. 1 negative, should be the same as that under density 1.800 of No. 3. If my measures are to be taken, then No. 1 negative should be placed only 5.39 times further away from the light than No. 3.

This test was applied, with the results which are instructive and confirmatory of my measures, and which I show. With the first-named distance, the fog density of No. 1 had scarcely permitted any printing action; but the light passing through density 1.800 had greatly blackened the paper. With the last-named distances derived from my measures the two are equal to the eye, and when the blackness is measured by the method I have often described, the print from the part of No. 1 negative, which represents fog, reflected 52 per cent. of white light; whilst the print from that part of negative No. 3, which had the greatest density, reflected 50 per cent. of white light, which are practically the same. The prints are before you. No. 3 negative was placed, in both cases, at 20 inches from the points of an arc light, and the other negatives at distances of 159 inches and 108 inches respectively, and both in approximately the same line and on a level with points.

In No. 1 there is a density marked by Messrs. Hurter and Driffield as .415, through which I make the light trans-

mitted to be .392. I compared this density with that of their density 1.800 in No. 3, which, as before, I made transmit .031 of the total light. If my measures were correct, then if No. 3 negative was placed 20 inches away from the light, and No. 1 placed 71 inches away, the blackness produced by these two densities should be the same. The results are before you; it will be seen that they are alike. Again, from a scale of blackness produced by light of different intensities it was easy to arrive at the light giving that blackness under No. 1 negative. The light transmitted through the various densities on No. 1 I have found to be: fog, .101; 10 sec., .63; 20 sec., .44; 40 sec., .30; 1; 80 sec., .19; 2; making this comparable with No. 1, we have: fog, .900; 10 sec., .556; 20 sec., .402; 40 sec., .268; 80 sec., .171, which is not unlike the Table I.

It may be urged that Messrs. Hurter and Driffield's measures may still be right, and that the lack of concordance is due to a variation in the photographic and optical densities. Now, if one thing is more certain than another, it is that a photographic density *can never be less than its optical density*. It may be, and often is, greater. If it were greater, then Messrs. Hurter and Driffield's measures being taken as correct, No. 1 negative ought to have been moved *further away from the light*, as No. 3 would be comparatively more dense, which would have made the results worse. If the photographic density had been greater than the optical density when my measures were used, the blackening under No. 3 negative would have been less than that under No. 1 at the parts compared; but it is not so.

I think these last experiments are fairly conclusive, at least they are to myself and to those who have so far seen the measures and the results, and I hope they may be equally so to the meeting. I have now twice given proofs of the correctness of the sector photometer; and twice given proofs of the incorrectness of the measures made by their grease-spot photometer, once by measuring negatives made by myself, and once by measuring new negatives which they themselves have measured. I consider now that any further proofs on my part are unnecessary, until Messrs. Hurter and Driffield can indicate error in what I have said regarding my photometer and their own. The methods of proving the truth or the contrary are in the hands of those who are interested in the subject, and, so far as I am concerned, I leave the matter to them. I think that before any definitely accepted theory can be applied as to the inter-dependence of density and exposure either in negatives or in positives it is necessary that the mode of measuring densities should be above suspicion, and certainly this is not the case in the method adopted by Messrs. Hurter and Driffield. They have shown by weighing the deposit on a negative that amount of silver varies with the optical density of deposit as arrived at by their measures which are in fault, and if so that part of their theory will not hold. I have believed otherwise, my belief having been arrived at before they published their paper.

I admire, as I have said before, the way in which their investigations have been carried out, and there is much that I agree with in their original paper; but I believe that they have introduced a fatal mistake, which they will have to rectify when they become fully conscious of what that mistake entails.

THE SECTOR AND GREASE-SPOT PHOTOMETERS AND THEIR RESULTS.

BY F. HURTER, F.R.S., AND V. C. DRIFFIELD.

It will be within the recollection of the Section that, in a paper read at the end of last session, we very briefly criticised an instrument which Captain Abney devised for measuring the transparencies of negatives. In consequence, Captain Abney practically accuses us of having, to use his own words, "blown upon" his instrument without sufficient investigation. Such a proceeding on our part would have been most unjust, and we hope that our present paper will prove to the satisfaction of this Society that the charge is perfectly groundless.

* In the tables it seems they show the density of each part as its measured density less the measured density of the general fog of the plate. If this be not so, then their case is worse than it will appear to be from the succeeding results.

In our former paper we based our criticisms entirely on experimental grounds; our conclusions were, however, even more strongly based upon an investigation of the results Captain Abney obtained by means of his photometer. Of these results we purposely said nothing; but the course Captain Abney has since seen fit to take, leaves us no alternative, but, in self-defence, to bring them forward. We shall therefore proceed to show that, by our experiments and by a careful analysis of Captain Abney's own researches, we were driven to the conclusion that we must warn our readers against the use of his instrument. We wish, at the same time, to answer disparaging criticisms of our own photometer and of our results. We shall do this as shortly as is consistent with the importance which has been attached, by many journals, to our paper.

The instrument which Captain Abney uses as a standard measure for light consists of a revolving disc with angular apertures which can be opened and closed whilst the disc is revolving, and which he shortly terms a "rotating sector." When this disc is caused to revolve in front of a lamp, a screen, illuminated by this lamp, appears darker and darker as the sector is gradually closed. The screen really receives the full intensity of the light but, owing to the rapid revolution of the sector, periods of illumination and periods of darkness intervene so rapidly that, to the eye, they coalesce and produce the impression of continuous illumination of lesser intensity; and the real question at issue is: can the eye judge the exact arithmetical average of the various intensities of light which act upon the nerves in rapid succession? If the eye can do this, the rotating sector is a perfect photometer and our criticism was unjust; but, if the eye cannot do this, our criticism was just, and the angular aperture of a rotating sector is not an accurate measure of light intensity.

Now, if the aperture of the sector be large enough and the sector be at rest, a lamp placed behind it will illuminate a portion of a screen with the same intensity as if the sector were not present. On revolving the sectors slowly, the eye still perceives that intensity as long as it can follow the image of the sector opening on the screen; as the revolutions are increased and the eye can no longer follow the image of the sector opening, a complete circle of light of considerably reduced intensity is the visible result. If the opening of the sector extend over half the circumference (180°) and the revolutions be made very rapidly indeed, a point is reached when the intensity of this circle of light approaches more and more nearly the exact half of the intensity of direct illumination of the lamp. It requires, however, from 4,000 to 5,000 revolutions per minute to attain this result. Diagram No. 1 shows how, with

increasing revolutions, a sector of 90° opening (two openings of 45° each) gradually gave light of less and less intensity. This was measured by the grease-spot photometer, the first measurement being made at 900 revolutions per minute. The curve between this point and complete rest is imaginary only, and simply indicates the alteration in intensity which must take place as the sector passes from complete rest to 900 revolutions per minute. A sector

opening of 90° should, of course, give 25 per cent. of the original light intensity, but it will be seen from this diagram that this fraction of the original intensity was only reached when upwards of 4,000 revolutions of the sector were attained.

We consider it a most serious objection to the rotating sector that its indications depend upon the number of its revolutions.

With large openings of the sector the task which the eye has to perform is comparatively simple. It receives a number of impressions of the full intensity of the light interrupted by periods of darkness, and it has to average these. But the task becomes more difficult as the openings become smaller. Diagram No. 2 represents the

light intensities measured by the grease-spot photometer as the opening of the sector revolves slowly past a line joining the grease-spot and the centre of the flame. The abscissæ represent the various positions of the sector in angular measure, 0 being the position when the sector opening was bisected by the line joining grease-spot and flame. The diagram shows the variations of illumination which the grease-spot received when sectors of different angular openings, viz. 60° , 30° , 11° , and 5° , were interposed. It will be seen that, with the largest opening of 60° , there was measurable light, not for 60° , but for 76° of its revolution. The full intensity of the light of the lump (taken as 100) is maintained during 45° to 46° of the revolution.

The light gradually grows from darkness at one end, and gradually diminishes to darkness again at the other. These periods of growth to and from the full intensity we called in our paper the "semi-shadow at both edges of the sector opening." As the sector opening is reduced, a point is reached when the full intensity of the light is no longer obtained; an opening of 11° giving only 81 per cent. of the full intensity, and one of 5° only 51 per cent., the semi-shadow being all that is left. The total amount of light which reaches the grease-spot during the complete passage of the sector opening is proportional to the sector opening; it is so theoretically, and it is so practically. The areas of these diagrams were measured by means of Amster's planimeter, and the following results were obtained:—A rectangle, shown in dotted lines on the diagram, one side being equal to 60° and the other side to the full intensity of the light, measured 2,938 = 60° . The diagram for 60° measured 2,942 = $60^\circ 1'$; for 30° , 1,445 = $29^\circ 5'$; for 11° , 469 = $9^\circ 5'$; for 5° , 229 = $4^\circ 9'$. These measurements leave no doubt that the amount of light transmitted by a revolving sector is proportional to the opening of the sector. This may also be proved by means of photographic plates. If the light passing through a revolving sector fall upon a sensitive plate, the number of revolutions will have no effect so long as every point of the plate receives each intensity equally often.

When, however, we tried to average these rapidly varying intensities by means of the eye, we found that it was not equal to the task. We still hoped that the eye might prove capable of averaging alternate periods of

illumination and darkness with tolerable accuracy if the intensity of the light itself were constant, as it would be if the source of light were a luminous point or a bundle of parallel rays; but we found that, even in this case, the eye is unable to average correctly, as we shall now proceed to show you practically.

For this purpose we shall employ an ordinary optical lantern, which is our source of light. We place in it a black disc having two openings of equal angular dimensions. Upon causing this disc to revolve, we produce two concentric circles of equal light intensities. This proves that our apparatus does not introduce errors, in that the two equal openings in the disc produce upon the eye equal effects.

In order to show you the difference between the two intensities due to openings of 60 and 70°, we place into the lantern another disc having such openings. The difference is, of course, small, but you will probably have no difficulty in deciding which intensity is due to the 60° and which to the 70° opening. We show you this in order that in our next slide you may be prepared not to look for any very striking difference.

We now place the third slide into the lantern and leave it to you to decide which circle of light, if either, is the brighter.*

We ourselves think the inner circle decidedly the brighter; but assuming them to be equal in intensity, they clearly demonstrate the errors of the sector for this reason:—The inner circle has a single opening of 60°; the outer circle has six openings of 12° each, or a total of 72°; yet it was this inner circle which was, if anything, the brighter. This clearly proves that, to the eye, 6×12 is not equal to 72, but is more nearly equal to 60. So much for the effect upon the eye. Upon a sensitive plate, however, the effect is different, the action of the light being strictly proportional to these openings. We produce a plate exposed to the action of light passing through this same disc, and the resulting densities measure, for the inner circle of 60°, 0.820, and for the outer circle of 72°, 0.920.

These experiences point to but one conclusion, viz., that the impressions made on the eye by rapidly changing intensities of light are not sufficiently accurate to serve as basis for photometric experiments. Captain Abney claims great accuracy for his apparatus, and we ourselves stated that its errors only became seriously appreciable in the case of high densities; but an analysis of his results obtained by means of it, and of which we proceed to give a short epitome, entirely corroborates the experimental proof we have given that the rotating sector is not a reliable instrument of research.

Captain Abney, like ourselves, investigated the action of light on sensitive plates, and, from measurements made with the sectors, he arrived at a law which expresses the relation of transparency to the number of a hole in a particular sensitometer which he uses. After making the necessary algebraical transformations in order to substitute the relative intensity of the light for the purely arbitrary number of the hole, the formula stands thus:—

$$T = 1 - u (\log. I)^2,$$

Taking logarithms on both sides we find—

$$- \log. T = u (\log. I)^2,$$

u being a constant and I the intensity of light which produced the transparency T , the unit of light being that due to the sensitometer hole which just failed, on development of the plate, to produce any deposit. This law Captain Abney terms the "law of error," and upon examination it leads to very extraordinary conclusions. It tells us, in the first place, that as the intensity of the light is increased indefinitely, the transparency diminishes indefinitely also; that is, the amount of silver on the plate increases indefinitely and without limit with increased exposure. The camera would, if this were true, become

a kind of alchemistic laboratory wherein silver may be produced from nothing. Captain Abney knows perfectly well that the density of a negative is limited by the amount of silver placed on the plate by the manufacturer, and we trust he will now see reason to doubt the truth of a law which leads to so absurd a conclusion. If this were the only fault to be found with his law, it would be of comparatively little consequence, as many other laws, generally accepted, lead to similar absurdities when pushed to extremes.

A much more serious objection to the formula, as a law, is that symbols enter into it, the meaning of which is ill-defined. It starts from a perfectly arbitrary number of a hole in a particular sensitometer, and it contains a constant of which we do not know the meaning. The real truth of the formula is this: The law, when deprived of its transcendental character, represents a parabola; and, given a short piece of any curve having no singular point, it is always easy to find a parabola which resembles it as closely as desired; for it is always possible to lay a parabola through four points of any given curve, and that is all Captain Abney can claim for his formula.*

Captain Abney further showed that if the quantity of silver on a plate be gradually increased, the transparency follows the same law—

$$T = e^{-m (\log. Q)^2},$$

which is again our algebraic transformation of his. From this law an equally absurd conclusion follows as from the last, and that without pushing the formula to extremes. According to Captain Abney's results, if we were to super-impose on a plate which permitted 26 per cent. of light to pass another plate of equal density (i.e., double the amount of silver), the combination would allow 12.3 per cent. of the original light to pass. (Photographic News 33, 634, gives the necessary data for this calculation.) Thus the second plate becomes greatly more transparent than it would be if used as a first since it allows $12.3 = 47.3$ per cent. of the light which it receives to pass.

This result is amazing indeed; the more silver we deposit on the plate the more transparent becomes each single unit of silver! We need not say that this is in direct contradiction to all researches hitherto made in this direction. With ordinary transparent media Bunsen and Roscoe, and Vierordt also, proved those laws which we gave in our former paper, and we shall presently see that a negative behaves almost exactly like a deeply-coloured transparent solution.

By a combination of the results of these two investigations Captain Abney arrives at the deduction that the amount of silver reduced by the light and subsequent development is simply proportional to the intensity of the light which acted on the plate. This conclusion cannot be deduced mathematically from his formula; nor is it true, except for very short illuminations, or very feeble intensities of light.

Then Captain Abney showed that a plate, after intensification, still obeyed the "law of error." After the necessary algebraic transformations of his formula, the relation between the transparencies of the intensified plate and of the original plate is simply expressed—

$$\begin{aligned} - \log. T_1 &= 0.01015 \\ - \log. T_0 &= 0.00603 = 1.68. \end{aligned}$$

It will perhaps be remembered that we called the negative logarithm of the transparency T the density, and that, for an intensified plate, we also made the assertion that the ratio of densities was constant. When, however, we examine Captain Abney's numerical results, we find that they deviate very considerably from this constant ratio, the deviations ranging from 1.0 to 2.27, the true mean being 1.64. From these large deviations we judge that the rotating sector is not so accurate a tool, even in Captain Abney's hands, as the grease-spot photometer is in our own. And when our critics find fault with deviations

* Opinion was divided; some members thinking the inner circle the brighter, others the outer circle, and others again that they were equal in intensity. All agreed, however, that the difference between the two circles was decidedly less than in the case of the second slide.

* Our results, however, clearly show that this curve cannot be a parabola.

in ratios of 5 per cent., we think we may fairly point to these results which deviate from 30 per cent. to 40 per cent. from the mean.

A further very curious result is brought to light if the "law of error," as applied to quantity of silver, be combined with the "law of error," as applied to intensification. It is not difficult to combine them, and we will only say that the result of so doing is that a given atom of silver will precipitate, from a solution of mercuric chloride, various amounts of mercury which depend upon the number of the sensitometer hole behind which that atom of silver was reduced. This, of course, is utterly untrue; it is entirely opposed to all chemical experience, and, in the face of Mr. Chapman Jones' researches on intensification, it is simply absurd.

We trust we have now said sufficient to prove to the Society that we have not warned our readers against the use of the rotating sector without cause. We are certain that Captain Abney is as able an experimental investigator as anyone living, and we ascribe these erroneous results solely to the faulty measuring instrument which it has been his misfortune to adopt.

We have ourselves, on the other hand, made use of the grease-spot photometer throughout our research. We asserted that its indications were proportional to the weight of silver on the plate, and we never made any claim that it was absolutely accurate, or that it measured the whole of the light transmitted in all directions by the negative. The main practical result of our investigations, which we communicated to the Society, was a method of determining the speed of a sensitive plate. As the results of our investigations have been called into question, owing to some alleged inaccuracy in the measurements of the plates, we have made a determination of the speed of a plate both by gravimetric analysis and by photometric measurements. For this purpose we used four half-plates, exposed respectively for 10, 20, 40, and 80 seconds to a standard candle at a distance of one metre. The four plates were developed together, and, after carefully fixing, washing and drying, they were measured photometrically. The films were then removed from the plates, and the silver determined. The results obtained were as follows:—

Exposure C.M.S.	Measured Density.	Calculated Density.	Weight of Silver Chloride.
10	0.525	0.525	Gm. 0.0163
20	0.960	0.963	0.0299
40	1.170	1.449	0.0450
80	1.970	1.968	0.0611

On the assumption that density, as indicated by photometric measurement of plates developed with ferrous oxalate, is proportional to the weight of silver, the densities calculated from the weights are as given in the above table. Diagram No. 3 shows the graphic method of finding the inertia of

the plate, and the absolute coincidence of the gravimetric and photometric results proves the extent to which the grease-spot photometer may be relied upon; and it also proves that there is, as we asserted there was, a range of exposures during which the weight of silver reduced by the light is proportional to the logarithm of the exposure. This is proved by the almost entire coincidence of the points and the straight line drawn through them. The abscissæ are the logarithms of the exposures, and the ordinates the milligrammes of silver chloride weighed. This experiment, we consider, disposes, once for all, of the adverse criticism which has been passed upon our photometer.

Captain Abney has discovered that negatives "scatter" so much light that our instrument cannot possibly measure all the light which a negative transmits; and owing to our instrument measuring the correct amount of light transmitted directly plus an excess of "scattered" light, as he told the Camera Club, we ought to find the transparency too great. But, in his criticism in the Journal of this Society, he found that a negative, measured by our method, gave a transparency of $\frac{1}{100}$ which, when measured by his "new and correct" plan (still using the sector) transmitted one-fortieth of the light. These criticisms, which are in direct antagonism, demand no reply.

In connexion with this "scattering" of light we wish to show you one or two experiments made by Captain Abney to prove what he thinks an insurmountable difficulty in our method of measuring plates.

We project upon the screen, by means of a lantern, a well-defined disc of light. Holding in front of the lens a piece of ground glass, this disc absolutely disappears and the light is now spread over the whole screen. This phenomenon is what Captain Abney terms the "scattering" of light. The fact is that the ground glass has itself become a source of light, and in calculating intensities of light as from this source, the distance of the illuminated screen would have to be measured from this ground glass.

If two pieces of the ground glass be placed in front of the lens, you will see that the general illumination is but slightly diminished.

If, instead of the ground glass, we place in front of the lens a solution of ammonio-cupric sulphate, the phenomenon is essentially different. The disc of light remains as it was (except that it is blue), and there is a very faint general illumination of the screen. Simply breathing upon the cell containing the solution will produce the "scattering" effect.

We now exchange this solution for a fairly dense negative which measures about 1.8, and again the phenomenon is slightly different. A well-defined disc of light is the most conspicuous effect, and around this disc you will perceive a halo of diffused light. There can be no doubt, however, that this phenomenon resembles much more closely that produced by the transparent solution than by the ground glass.

If a second negative of the same density be now placed in front of the first, both the disc and the halo are very considerably reduced in intensity—in fact vanish—which was not the case with the ground glass. This proves that both the directly transmitted light and the scattered light diminish, as the amount of silver on the negative is increased. And if, as in our photometer, the distance of the illuminated screen from the source of light and from the "scattering" negative be identically the same, then the total intensity of the light both "scattered" and directly transmitted by the negative, diminishes as the silver is increased, in accordance with the laws which we published in our former paper.

Many other criticisms have been passed on our paper which are too frivolous to call for notice, though we may just instance one respecting our use of logarithms and the effect which the employment of other systems of logarithms would have had upon our results. We would, in reply, to this, simply refer our critic to Chapter XVII. of Knight and Hall's Algebra.

We admit that, to many of the readers of our paper, the use we made of the word density proved a stumbling block. We can now see that if we had converted all the results into

milligrammes of silver, we should have been better understood. Our "density" is in reality, however, synonymous with weight of silver.

It was by referring our results to weight of silver that we discovered that important and interesting curve, the characteristic curve of the sensitive plate. No other way of stating the results; no other method of plotting this curve would ever have revealed such a simple and important explanation of photographic phenomena. On this ground alone we claim a distinct score for our grease-spot photometer. The "law of error" is, on the other hand, utterly opposed to the photographer's every-day experience of the existence of distinct periods of under-, correct-, and over-exposure.

Another very important fact brought to light by means of the grease-spot photometer is that the photographer has no power to alter the ratio of the weights of silver reduced in various parts of the negative by alterations in development. These ratios are due to the action of the light alone.

To this statement many have taken exception, notably Mr. Chapman Jones, who, while he agrees with us that under-exposure cannot be corrected by development, still believes that, in some measure, over-exposure can be remedied. To prove this he made an experiment, and sent us the plates for measurement. The experiment consisted in illuminating two plates equally by means of a sensitometer, so as to obtain a similar series of gradations on each plate. The time of exposure was, in the case of both plates, 30 times that needed to give a perceptible deposit with the smallest hole of the sensitometer. The light intensities ranged from 1 to 775. One plate (No. 7) was developed for two minutes in a strong developer of soda and pyrogallol. The other plate (No. 8) was first immersed in a solution of potassium bromide, and the entire development occupied no less than 38 minutes, the alkali being added in minute quantities from time to time. Of this experiment Mr. Chapman Jones wrote:—"Thus in Plate 8 I did the best I could to remedy the evil of over-exposure." Diagram No. 4 shows you how far he succeeded. The

curve No. 7 is a mean path on which the points which indicate the densities, as measured on Plate No. 7, ought to have been situated. The higher curve, No. 8, is exactly the same curve as No. 7, each ordinate being multiplied by the mean density ratio 1.54. This simply means that, had the development of Plate No. 7 been prolonged for one minute, the densities of Plate No. 7 would have been situated on the same curve as are those of Plate No. 8. In other words, Mr. Chapman Jones, in doing his best to remedy the evil of over-exposure, only succeeded in making one plate generally denser than the other, but the ratios of the silver deposited are, on the whole, the same in Plate No. 8 as in Plate No. 7. The density ratio between the extremes of Plate No. 7 is 3.22, that between the extremes of Plate No. 8 is 3.25, so that the density ratio was increased by less than 1 per cent. We do not therefore think that Mr. Chapman Jones can claim to have remedied the evil of over-exposure, considering that a correct representation of his light intensity would have demanded a density ratio between the extremes of at least 1:30.

This experiment clearly shows the inability, even of an expert, to correct over-exposure in development. Mr. Chapman Jones does not agree with us, however, because he regards the errors in these results as evidence that he has done something to remedy over-exposure. But when we arrange the true density ratios of the corresponding squares of Plates Nos. 7 and 8 in their original sequence on the plate, as we have done in Diagram No. 5, the errors

Diagram N^o 5.

1	2	3	4	MEAN
1.60	1.48	1.29	1.50	1.47
8	7	6	5	
1.67	1.54	1.32	1.52	1.51
9	10	11	12	
1.69	1.52	1.50	1.57	1.57
16	15	14	13	
1.66	1.55	1.51	1.61	1.58
17	18	19	20	
1.70	1.52	1.52	1.61	1.59

group themselves in such a way as to leave no doubt that they are due, almost entirely, to inequalities in the coating of the plates, particularly on the left-hand margin, where it will be seen the highest density ratios all lie. In our former paper we pointed out that inequalities in the coating of the plate constitute the most serious source of error of all. Mr. Chapman Jones bases his claim to have remedied over-exposure chiefly upon the averages of four groups, each consisting of five consecutive density ratios. The diagram will show the fallacy of such a proceeding, as two of the groups each include two of the high marginal density ratios, one group includes only one, and the fourth group does not include any at all. The averages of five groups, each consisting of four consecutive density ratios, as indicated on the diagram, fail altogether to support Mr. Chapman Jones' claim.

We ourselves consider that this experiment upon which Mr. Chapman Jones exerted his utmost skill a most striking proof of our assertions, and, as experiments of this kind are most welcome to us, we here record our thanks to him for the trouble he has taken to put our conclusions to a practical test.

We will conclude this paper with a quotation from an address by Captain Abney to the British Association at Newcastle. He said: "Photography deserves to have followers of the highest scientific calibre, and if only some more real physicists and chemists could be induced to unbend their minds and study the theory of an applied science which they often use for record or for pleasure, we might hope for some greater advance than has hitherto been possible."

We do not flatter ourselves that we are physicists or chemists of the highest scientific calibre, nor do we claim to have had Captain Abney's opportunities and experience in photographic matters; but we do claim, for our investigations, superiority over his, in that they are based upon a scientific and satisfactory nomenclature and system of units, and that they were carried out in such a way as to be capable of repetition by anybody else.

We claim also to have given formulae which, unlike Captain Abney's, lead to truth, explain photographic phenomena, and admit of practical application. We have had the misfortune to discover the errors of his results, and have thereby incurred his serious displeasure.

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

Meeting held on Friday, 9th January 1891.

MR. PETER HART, F.I.C., IN THE CHAIR.

SOME LABORATORY EXPERIENCES.

BY DR. B. W. GERLAND.

A.—THYMOL AS PRESERVATIVE FOR STANDARD SOLUTIONS OF OXALIC ACID AND TARTAR EMETIC.

THE convenience of oxalic acid as standard solution is counterbalanced by its tendency to decompose under uncontrollable circumstances. I have succeeded in preserving the solutions (normal and tenth normal) already for two years by adding a small crystal of thymol. This does not interfere with its use for standardising alkaline solutions. Permanganate also acts normally on the solution containing thymol either cold or warm, but a short time after the pink has become established, the solution turns muddy brown. Nevertheless the value of the solution against permanganate is the same, whether it contained thymol or not, as long as the quantity of permanganate necessary to produce the pink colour is taken.

The standard solution of tartar emetic which I use in my process for the estimation of tannin is also preserved by a small quantity of thymol without interfering with its use.

B.—ESTIMATION OF BASICITY OF SOLUTIONS OF ALUMINIUM SALTS.

The determination of the excess of acid in an aluminium salt by titration with soda using methyl orange as indicator, has been repeatedly recommended. I have for a long time availed myself of this valuable indicator for estimating the basicity of aluminium salts by titration with a mineral acid. I prefer for this purpose to measure off twice the same quantity in two similar beakers, colour both equally very faintly with the methyl orange and add the standard acid (nitric, hydrochloric, or sulphuric acid) until the pink has become constant. After a while the pink changes again to yellow, but for the last drops so slowly that the distinction of the colour becomes difficult. This operation is facilitated by having the two samples before the eyes and adding alternately a drop of the standard acid to the one and the other until both retain the same shade of pink.

In this operation the first quantity of acid added colours the liquid pink for an instant, which changes quickly to yellow, but the more the point of neutrality is approached the slower this takes place, so that for the last drops hours are required to produce the chemical equilibrium, and sometimes midsummer day would not be long enough to finish the test with the strictest accuracy. It is this

surprising retardation of chemical reaction between the substances in solution which induced me to mention the matter here.

The titration is expedited by heat. If it should be preferred to add at once an excess of standard acid and measure the excess of the same by standard alkali, it is preferable to use an alkaline carbonate, as this precipitates the alumina in a more flocculent form, which is redissolved quicker than with caustic alkali.

C.—OBSERVATIONS WITH BLEACHING LIQUOR AND SOLUTIONS OF BLEACHING POWDER.

Many years ago I tested daily the casks of bleaching liquor which were delivered by two firms. The liquor from one firm was invariably normal in its behaviour and contained the stipulated quantity of chlorine. It was delivered through the railway carriers, and may have been days old. The other firm delivered their liquor at odd times in a warm state, and as a rule with only 5 per cent. chlorine. They were both tested in the same way by adding excess of one-tenth standard arsenite, starch paste, and titrating back with standard iodine solution. To my amazement I found that the liquor appeared the poorer the quicker the process was worked, so that after some practice the 5 per cent. liquor could be made to yield only 2 per cent. of chlorine. Having no time to investigate this surprising behaviour I communicated and demonstrated these observations to several chemical friends, but so far have not had the satisfaction to see them supported by others.

After some time the bleaching liquor was replaced by solutions of bleaching powder produced at the works, and I interested myself in the behaviour of this solution, but could never find any material change in its strength from the time of its production to the age of seven days, except, as was to be expected, a slight deterioration.

About the same time this solution was used for the oxidation of an organic substance in alkaline solution. This process took a characteristic course. After mixing, the temperature rose gradually to 40°, and then at a highly accelerated rate until, if no special attention was paid, it would come to a violent boil and the experiment was lost. But the course of reaction was so regular that, after having once learned to manage it, I had no mishap in the great number of operation conducted in the course of several years. The reaction completed, the solution contained no more hypochlorite. This operation was taken up again after long interruption, but now its course was essentially different.

After the mixing, the temperature did rise, but much slower than before, and would retrograde before the 40° was reached, whilst the liquor still contained hypochlorite, and no further reaction would take place. Accidentally I treated a part in a copper vessel, and after a time the process started again and continued under the same phenomena as before. This induced me to add a minimal quantity of a copper salt to the bulk of the mixture in the wooden vat, and the result was that the reaction set in and continued under rise of temperature until all hypochlorite had disappeared, and the result was the same I had been accustomed to in former years.

I took much pains in inquiring about the materials used formerly and now, and could only arrive at the conclusion, with a high degree of probability, that the only difference was that in the older manipulations bleaching powder, made by the Deacon process, whilst for the recent ones certainly bleaching powder made by the Weldon process, was used.

It is not improbable that in the Deacon process minimal quantities of copper are carried off by the gases and become fixed in the bleaching powder. I have never noticed any statement to that effect nor anything alluding to a different behaviour of bleaching liquors and solutions of bleaching powder.

Induced by this experience I turned my attention again to the solutions of bleaching powder, and found that the numbers of samples tested increased in strength by 0.2 to 0.4 per cent. for the 6.5 per cent. solution in the course of a few days.

These observations suggest a number of questions of theoretical as well as practical interest, which I should have gladly worked upon had not circumstances interfered and deprived me of my opportunities and preparations.

To any chemist inclined to take up this investigation I heartily wish success and give him the assurance that I have most carefully tested and taken extensive precautions to avoid self-delusion in my observations on account of the unexpected and so far unaccountable results.

DISCUSSION.

The CHAIRMAN wished to know what was the advantage of oxalic acid over other acids as a standard solution?

Dr. GROSSMANN said: While he had not had any experience of bleaching powder made by Deacon's process he had had some years' experience of the Weldon process, and as far as Weldon bleach was concerned he had always found that its solution lost strength on standing. Bleaching powder in the solid state would also deteriorate in time, and it was said that it would sometimes decompose suddenly with strong evolution of oxygen, and so violently as to resemble an explosion. Weak old bleaching powder generally contained chlorate, and if the temperature in the chambers was allowed to rise too high, fresh bleach would also contain chlorate. It would depend upon the way in which it was tested whether the chlorate present would appear in the test as active chlorine, or not at all. Dr. Gerland's observation that copper salts caused an evolution of oxygen might be due to the acidity of the copper compound, but if that were not the reason it would be very important to carry these experiments further and see what other compounds would have the same effect. In the manufacture of chlorate of potash there was always an evolution of oxygen, even if the temperature were carefully regulated; and the question arose whether this might not be due to the presence of minute quantities of copper, or other compounds of like properties, in the lime used for the purpose.

Dr. GERLAND, in reply, said that the presence of chlorate could not have interfered with the results because there was always a large excess of alkali or milk of lime present. The spontaneous decomposition of bleaching powder was, in his opinion, caused by the evolution of free oxygen, and that the formation of chlorate was quite subordinate. The explosions referred to were caused by the evolution of free oxygen. The thymol acted as a preservative on the solution of tartar emetic used by him for the estimation of tannin.

TURKEY RED OIL.

BY J. ARTHUR WILSON.

Historical.—Turkey Red oil, the product of the reaction of sulphuric acid and castor or olive oil, was introduced about the year 1876, at least so far as being placed on the market is concerned. It is probable, however, that it was made secretly some time previous to this. In 1874 there appeared the so-called soluble oil, made by the saponification of castor oil by caustic soda, and hence consisting of the sodium salts of ricinoleic and iso-ricinoleic acid.

Mercer and Greenwood patented the product of the reaction of sulphuric acid and olive oil, and it is said that the German chemist Runge prepared this compound even still earlier; but who was the first to suggest the use of castor oil in place of olive oil is not positively known. Turkey Red oil was originally intended for use in the fabrication of Turkey Reds, and hence possess the exclusive right to the name Turkey Red oil, although scientifically speaking it is not correct. In commerce it is usually called oleine, a term somewhat confusing, it being different from the olein of fats, or the olein of Yorkshire grease.

Manufacture.—The manufacture of Turkey Red oil is a comparatively simple operation; it requires no expensive plant, and very little skilled labour, although there are several details to be attended to. It may be divided into two parts—

1. *Hydrolysis of the Fatty Oil.*

2. *Purification of the Products of the Interaction and Partial Neutralisation.*

The first operation takes place in rectangular wooden vessels, occasionally lined with lead, and preferably fitted with an apparatus for agitation of the contents of the vats. These vats are fitted with stop-cocks at suitable heights in order to run off the wash-waters and the finished products. Castor oil (if castor Turkey Red oil is desired) is run off, and the contents gauged, the weight of which may be found from the specific gravity of the oil. The proper quantity of oil of vitriol is then added slowly, the whole contents being thoroughly agitated by means of the apparatus, or in default of this by large paddles made of wood. The amount of vitriol used varies from 15 to as much as 40 per cent. of the weight of oil, being most in winter and least in summer, and both of which differ according to the practice of the manufacturer. Again, some add the whole of the vitriol at one time, others at two periods, one half on one day, and the other the day following. The heat is not allowed to get too high, which would produce a dark-coloured product; but in any case, evolution of sulphur dioxide is perceived by the smell, but it probably results from decomposition of the aluminoids and other extraneous matters of the oil. After allowing to stand another 12 or 24 hours, it is ready for washing.

This is done by hot water containing more or less common salt, in order to reduce to a minimum the loss due to solubility. Some makers work first with ordinary water and finally with brine.

In washing with brine, it is important not to commence with too hot a solution, otherwise the excess of vitriol produces chlorohydric acid, which decomposes the sulphated oil, and this is simply undoing what we have previously done. After the washing comes the neutralising, which is only done partially. Soda or ammonia are employed; the latter is to be preferred, although soda is more generally used.

Water is then added so as to make a finished product containing from 45 to 50 per cent. fatty matter; occasionally much less water is added, especially when for export.

The neutralisation is carried out so far that, about from one-fourth to less than one-half of the theoretical, the average composition is—

1.30 to 1.50 per cent. Na₂O.
20.0 to 27.0 per cent. free fatty acids,
25.0 combined acid and glycerides.

In producing high class Turkey Red oils, much more trouble is taken, but the above is the plan usually followed. In summer time, Turkey Red oil occasionally decomposes with separation into fatty matter and water, together with an odour of fermentation. On one occasion I took some of an oil thus decomposed, and placed it on flour paste in a moist warm atmosphere, when the surface was instantly covered with a purple colouration as if a tar dye had been sprinkled on. This is similar to results often found on mildewed cotton, and caused by a variety of fungus not thoroughly studied. It is very important that Turkey Red oil should not be too acid, otherwise it will not bear the addition of a proper amount of tin compounds in the preparing liquors.

Applications.—Turkey Red oil, as its name implies, is used in the initial preparation or mordanting of Turkey Reds, but it is used in the final production of ordinary Alizarin Reds, and in the mordanting of cloth for extrinet and steam styles in calico printing. The process for producing Turkey Reds may be briefly stated as follows:—The previously well-bleached pieces are passed through a liquid prepared from Turkey Red oil, aluminate of soda, stannous chloride and ammonia, and dried. Then they are passed through a solution of alum once or twice and again dried, and kept in a properly constructed room to age. They are then passed through cow-dung and arsenate of

soda, to fix the mordant and remove any excess, when they are ready for dyeing. After dyeing they are again prepared in Turkey Red oil, steamed with high or low pressure steam, and brightened by soaping, which completes the operation. Turkey Red oil is used in ordinary Alizarin reds only in the final operations of brightening. Thus the manufacture and application of Turkey Red oil is not an unimportant industry which absorbs a large quantity of the castor oil imported.

Constitution.—Turkey Red oil has been the subject of much investigation, but on account of the difficulties in this branch of research, the results contain much of a speculative character. Turkey Red oil may be manufactured from olive, cotton, or castor oil, but the latter alone has the legitimate right of the designation Turkey Red oil. We may therefore concentrate our attention on the product produced by the action of sulphuric acid on castor oil and of olive oil. Such a study divides itself into two parts, viz., action of sulphuric acid on ricinoleic acid and isoricinoleic acid and tricinolein. 2nd. Action of sulphuric acid on oleic acid and triolein, which are those peculiar to castor oil and olive oil respectively. Castor oil contains no oleic acid, whilst olive oil probably contains linoleic acid, although in small quantity.

The hydrolysis of a tryglyceride by an alkali such as alcoholic potash would be represented by the elementary equation—

but the action of sulphuric acid is not so simple, the products not being simply fatty acids forming the molecule of the triglyceride and glycerol, but they contain sulphur in combination in some form or other; and it is here that the opinion of chemists who have studied the question are divided. The question as to completion of the hydrolysis under the conditions which obtain in the manufacture of Turkey Red oil are shown thus:—

Sulphuric Acid used.	Free Fatty Acid = Sulphoricinoleic Acid.
Per Cent. 12.5 by weight.	Per Cent. 30.4
25.0 "	55.5

The percentage of free acid, and hence the progress of the reaction, is not quite proportional to the acid used. But from the composition of the Turkey Red oil it is possible to tell approximately how much vitriol has been used in its fabrication. A 45 per cent. Turkey Red oil usually contains 25 per cent. free acid, and the matter separated from such an oil by acid and salt solution usually contains—

	Per Cent.
Free fatty acids as sulphoricinoleic	78.5
Glycerides as tricinolein	25.5
	<u>103.8</u>

so that after making allowance for free acid existing in the oil, about one-third of vitriol is commonly used, although considerably less than this is occasionally used.

The fatty matter of Turkey Red oil is divided into two classes, viz., those soluble in water and those insoluble in water. Luehti and Suida believe that the soluble part of Turkey Red oil from olive oil consist of glycerol sulphates, one of which is derived from hydroxystearic acid, $C_{18}H_{35}O_3$, and the other from an hydroxyoleic acid—

Such a view is, however, untenable, from the fact that oleic acid gives the same product as triolein, in the former case of which no glycerol is present, and also that from Turkey Red oil only the most minute traces of glycerol can

be obtained, and that such bodies would be neutral and not acid as is the case. The only two other possible views are those of Müller-Jacobs and of Benedikt. The latter believes that the compounds are not true sulphonic acids, but similar in constitution to the bodies known as sulphuric esters. Müller-Jacobs considers them to be true sulphonic acids.

The following formulae shows both these views in juxtaposition:—

Benedikt and Ulzer obtained the true sulphonic acid of a higher homologue of oleic acid synthetically and compared its properties with those of the Turkey Red oil acid. It is a yellow oil miscible with water in all proportions; it is unattacked by caustic alkalis and concentrated chlorhydric acid, whilst by the latter Turkey Red oil acids are decomposed into sulphuric acid and hydroxystearic acid. Benedikt and Ulzer, from this and other considerations, believe their theory correct, viz., that the soluble part of olive Turkey Red oil consists of hydroxystearin sulphate, that of castor Turkey Red oil of ricinolein sulphate.

Luehti and Suida have considered the soluble part of olive Turkey Red oil to consist of an acid sulphate of hydroxystearic acid, explaining the decomposition in the following manner:—

Oleic Acid, Hydric Sulphate. Hydroxystearin Hydrogen Sulphate.

Hydroxystearin Hydrogen Sulphate. Hydroxystearic Acid.

Benedikt and Ulzer have determined the quantity of hydroxy acid in Turkey Red oils of various origin by means of the acetyl process (some doubt has been thrown on the value of the acetyl process by Lewkowitsch, see the Proceedings of Chemical Society, 1890), and compared those with the theoretical values of hydroxystearic acid and ricinoleic acid. They have also determined the iodine values of the acid from olive Turkey Red oil and from castor Turkey Red oil, which results will be considered in the concluding part of this memoir.

The author's experiments on the conjoint fatty matter from castor Turkey Red oil show—

	Per Cent.
Free fatty acids (calculated as ricinoleic acid)...	78.5
Glycerides calculated as tricinolein.....	25.3
	<u>103.8</u>

which shows that acids of lower molecular weight are present. Olive Turkey Red oil in similar manner from a consideration of the alkali required on the one hand for neutralisation, and on the other for hydrolysis.

	Per Cent.
Free acid calculated to hydroxystearic acid	71.7
Triolein	24.8
	<u>96.5</u>

The regeneration of the primary acid, in the case of castor oil, ricinoleic and isoricinoleic acids, is not so easy as Benedikt supposes. Thus the mean combining weight of Turkey Red oil acids from castor oil after boiling with acid was 321, whilst ricinoleic acid would be 298.

Experiments made in the author's laboratory show that the greater the amount of sulphuric acid used in the fabrication of the Turkey Red oil, the lower the percentage of iodine assimilated, and presumably the less capacity for oxidation. Similarly, increase of hydrolytic agent means raising the melting point of the conjoint acids in the case of olive oil, whilst the reverse is the case with castor oil. Thus the acids from olive Turkey Red oil prepared by half its weight of sulphuric acid have a melting point of 41° C. = 106° F., those of castor Turkey Red oil at about 34° F.

Benedikt and Ulzer, as a result of their experiments, show that the known superiority of Turkey Red oil from castor oil in Turkey Red dyeing is due to it consisting of the acid sulphate of a non-saturated acid, whilst on the other hand olive Turkey Red oil contains derivatives of a saturated acid; also, that on account of the acid prepared from olive Turkey Red oil absorbing no iodine, whilst the castor oil acid takes up 83 per cent., the latter has a greater capacity for oxidation, and hence is more suitable. Another fact must not be lost sight of, and that is emulsions of castor Turkey Red oil are in a much finer state of subdivision and hence in being taken up by the fabric offers a larger surface to oxidation.

Analysis.—The analysis of Turkey Red oil is divided in two parts, one of which it is proposed to deal with in a future paper:—1st. The estimation of the proportion of combined alkalis, free fatty acids, and of total fatty matters. 2nd. The examination of the fatty matters for purity. The latter is the most difficult, and it is intended to devote a special paper to the subject, when a large number of experiments now in progress are finished.

Specific Gravity.—The specific gravity of Turkey Red oil is very variable; it is best taken by means of the Westphal balance. In a 45 per cent. oil the limits may be—Maximum, 1.035; minimum, 1.017.

Estimation of Total Alkali.—5 to 7 grms. of the oil are diluted to about 50 cc., a few drops of methyl orange added, then half normal hydric sulphate till the usual reaction.

In a Turkey Red oil giving a deep milky emulsion with water, the percentage of Na_2O will be from 0.8 to 1 per cent. or even lower, whilst an oil giving only a moderate emulsion or none at all, the percentage of alkali (Na_2O) may be from 1.2 to 1.5.

Estimation of Free Fatty Acids.—The estimation of free fatty or fatty sulphuric acids in a Turkey Red oil neutralised by caustic soda is carried out in the usual manner with a few precautions. It is necessary to use much more alcohol or preferably a mixture of alcohol and ether; also, the temperature of the liquid during titration must be low on account of the great tendency to hydrolysis of the glycerides present in all Turkey Red oils, and the liquid must be rapidly agitated to prevent local action of the alkali. Semi-normal alcoholic potash is used for titration and phenolphthalein as indicator.

The average percentage of free fatty acid present calculated in terms of sulphuric acid, in a 45 per cent. oil may vary from 22 to 30 per cent.

In a Turkey Red oil, in which ammonia has been used for neutralising, a difficulty is encountered in the fact that the alkali used for titration liberates a quantity of the ammonia which may be lost if the temperature be above 60 $^{\circ}\text{F}$., and when we remember the reaction of ammonia towards phenolphthalein, we shall see that the end reaction is by no means sharp; nevertheless very good results may be got even in the case of ammonia Turkey Red oil.

Estimation of Total Fatty Matters.—The accurate estimation of total fatty matters in Turkey Red oil is a matter of some importance, and one in which considerable difference of opinion exists as to the best method of attaining the object in view. When we consider the constitution of Turkey Red oil it will be evident that the method of analysis used for other fatty bodies such as soap, are of little use without considerable modification. A crude form of test much used by manufacturers is the following:—“20 grms. of sample in a 200 cc. flask, add 20 cc. of water and 20 cc. of strong HCl , boil till the fatty matter floats quite clear on the aqueous liquid, pour into graduated jars, allow to cool, read off number of cc., which multiplied by 5 gives percentage.”

It is evident that the preceding test can at most be only roughly approximate, there being errors on both sides, loss due to solubility on the one hand, and on the other the fatty layer retains water, and volume is taken as weight. Much more satisfactory as a factory test is the following:—25 grms. of the sample is weighed out into a flask, the body of which holds about 100 cc., and the neck is graduated into centimetres and tenth of a centimetre. 50 cc. of

saturated salt solution added and 10 cc. of concentrated HCl , boil till clear, and add saturated salt solution till rather above the zero graduation, allow to cool, and read off the number of cc. from which the percentage is calculated.

Although the above tests may be suitable as a control in the manufacture of the oil, they are not suitable for purposes of valuation. I have therefore pleasure in submitting the following method as being equal or better than any hitherto published. It relies on the use of an immiscible solvent with subsequent treatment of the extract to remove extraneous matters.

Ten cc. of perfectly saturated salt solution are pipetted into a globular separator of about 100 cc. capacity, and from 5 to 6 grms. of the sample poured directly into the separator. About 0.5 cc. of HCl 1–2 is then added, and the whole thoroughly agitated, after which about 50 cc. of ether is added and again agitated. The ethereal layer is received into a dry flask, and the aqueous layer again agitated with about 25 cc. ether, which is received in the flask with the first extract. The ether is then evaporated and recovered, and the fatty matter in the flask dried by blowing dry air through about 10 minutes.

From 25 to 35 cc. of really absolute alcohol is then added, agitated and allowed to stand a short time, poured through a dry filter, the residue in flask washed two or three times by alcohol, and the filtrate and washings received in a tared flask, the alcohol evaporated and the residue kept on the water-bath about one hour, whilst a current of purified air is continuously passed through the flask. The residue is then weighed and the percentage calculated.

The functions of the alcohol treatment are: it enables the water taken up in all ethereal extractions to evaporate quickly and precipitates the sodium sulphate, leaving the fatty matters in as pure a condition as it is possible to attain.

I have tested a number of the extracts for ash by burning at a very low heat in platinum, and have never found more than 0.3 per cent. ash, and with proper manipulation as low as 0.1 per cent. ash.

DISCUSSION.

DR. C. O. WEBER: Mr. Wilson gave the quantity of sulphuric acid as ranging from 15 to 40 per cent. He thought this depended largely upon the temperature at which the oil was produced, and this should be kept as low as possible. The amount of sulphuric acid used was most important in the manufacture of Turkey Red oils, and the rise of temperature above a certain point produced decomposition not only of the albuminous matters, but also of the ricinoleic acid which was split in the molecule; and if they examined the oils which have been produced above 40°, they would find the products of the decomposition of the ricinoleic acid. To always get a product of the same quality it was desirable to use the same quantities of sulphuric acid; and if under these circumstances the temperature was found to rise above 40°, artificial cooling must be applied. He deprecated the use of brine for washing, because if used for the first washing, where there were large quantities of free sulphuric acid present, there was also large quantities of hydrochloric acid set free, which had a much stronger tendency to decompose ricinoleic acid than even sulphuric acid had. He would rather recommend washing with Glauber salt solution, which was absolutely innocuous. As far as his experience went, the excess of sulphuric acid used in the manufacture of Turkey Red oil made the use of any salt solution unnecessary, at any rate in the first washing. For the second or third washing it might be advisable to use Glauber salt solutions. In his opinion the theoretical side of the question was not far enough advanced to form any reliable judgment, but he did not think that sulphurous ethers were present to any large extent in Turkey Red oils, as in that case they would always be able to regenerate equivalent quantities of sulphuric acid, whereas on analysing Turkey Red oils they could not regenerate sulphuric acid, or very small quantities only. But this referred particularly to oils produced at low temperature; if the oils were produced at temperatures above 40° C. the case was somewhat different.

DR. BRUNNER: The decomposition product of ricinoleic acid was in no case valerician acid, but oenanthylic acid.

DR. WENER: With regard to the remarks just made, he had seven years ago seen considerable quantities of what was represented to him to be valerician acid produced from Turkey Red oils at high temperatures.

DR. J. GROSSMAN said it seemed to him very unlikely that with a mixture of strong sulphuric acid and salt at ordinary temperatures there should be hydrochloric acid set free.

DR. WENER: That hydrochloric acid was set free was absolutely certain, especially when used in the manner referred to by Mr. Wilson. If sulphuric acid be added to a hot or cold solution of salt, there could not be any doubt that hydrochloric acid was set free, and that would act upon the ricinoleic acid, as he knew from sad experience.

MR. W. THOMSON asked whether there was any distinct relation between the iodine absorption of Turkey Red oil and its capability of being oxidised.

MR. WILSON, in reply, said that both Glauber and common salt were used largely for washing purposes. If they were not used there was great loss due to solubility of the most valuable parts of the fatty acids. He was aware that occasionally nothing but water was used, except perhaps in the final washing, and this, as he had stated before, was only partly satisfactory. With regard to the production of hydrochloric acid in the first wash by action of the sulphuric acid on the common salt, he understood there was some doubt in their minds. He would say that it was beyond doubt, and on this account he would recommend the use of sulphate of soda in the first wash, if not altogether. In many cases it was best not to use water of too high a temperature to begin with, as he had mentioned in the paper. He had spent several days washing the fatty matters produced by the action of sulphuric acid on castor oil, and had found that to some extent there was a regeneration of the primary fatty acids and sulphuric acid by the action of fairly concentrated acids. As to the remarks made by Mr. Thomson with regard to the relationship between the iodine absorption of fatty acids and their tendency to oxidise, there were some marked exceptions to the usual rule, still in the majority of cases it was no doubt true.

MR. W. J. CHRYSAL IN THE CHAIR.

THE EFFECT OF EXPOSURE UNDER CERTAIN CONDITIONS UPON SOME CONSTANTS OF OILS.

BY H. BALLANTYNE.

THE object of the following experiments was to ascertain the effect of exposing different oils to the action of light and air, upon the so-called "constants" employed in the analysis of such fatty substances, with a view to determining which constants should be relied upon in examining oils of doubtful age.

As far as can be ascertained by a perusal of the literature on oil-analysis of the last 10 years, no systematic series of experiments has been made for the purpose of examining the effects of exposure upon oils. It is, of course, a well-known fact that long exposure to light and air causes an oil to become rancid and to liberate a quantity of free acid, and it is very generally understood that the rancidity is due to this liberation of free acid. Most oils are known to have their colours bleached by subjection to sunlight, and this fact is utilised to a certain extent in the refining of oils in commerce.

Occasionally one comes across notes of the abnormal figures given on analysis by old samples of particular oils. For instance, Allen (this Journal, 1886, 66), mentions that a sample of porpoise oil, having a specific gravity of 920, after standing for three years showed a gravity of 926, while no great increase of free acid was observed; another portion of the same oil, kept under different conditions, had increased in density to 932. It has also been noticed that the iodine absorption of rancid butter-fat is abnormal, but such peculiarities have occurred where the oil was either in a state of decomposition or was very old. It is hoped that, owing to their systematic nature, the following experiments may prove of value to those interested in oil-analysis.

The oils operated upon were olive, castor (first pressure), rape (colza), cotton seed, arachis (earth-nut), and linseed, these being six of the most important oils used in commerce. Of each of these, six quantities of about $3\frac{1}{4}$ oz. each were exposed in white glass bottles, thus:—

A. Kept in direct sunlight, uncorked, and agitated every morning.

B. Kept in direct sunlight, uncorked, but undisturbed.

C. Kept in direct sunlight in a corked bottle and undisturbed.

D. Kept in the dark, uncorked, and agitated every morning.

E. Kept in the dark, uncorked, but undisturbed.

F. Kept corked and undisturbed in the dark.

Thus quantities A. and D. would show in an exaggerated degree the results of exposure to both light and air, and air only, respectively, while B. and E. would indicate what alterations might be expected in ordinary sample bottles of oil under these circumstances, which had inadvertently been left uncorked.

As it was found that only series A. and C. were affected to any appreciable extent by this treatment, these two sets alone were tested regularly every month, the constants determined being the free acid, potash neutralising power, specific gravity and iodine absorption. The colour and

quality were also noted. At the end of six months the quantities B, D, E., and F. were examined in their density, iodine absorption, potash neutralising power and free acid, and Mammen's temperature test was performed on quantities A., C., D., and F.

In Table I. will be found a note of the alkali-neutralising power of and percentage of free acid in the original samples operated upon; the specific gravity, iodine equivalent and temperature reaction are referred to in their respective tables.

TABLE I.

	Olive No. 1.	Castor.	Rape.	Cotton Seed.	Arachis.	Linseed.	Olive No. 2.
	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Potash neutralising power	19.00	18.02	17.53	19.35	19.21	19.09	18.90
Free acid as oleic*	5.19	2.16	2.43	0.27	0.20	0.76	11.28

* The free acid is in all cases calculated to oleic acid for simplicity's sake.

The constants will now be dealt with individually.

1.—Free Acid.

There is a very prevalent belief among chemists that the rancidity of oils is due to the liberation of free acid by decomposition, and many references could be given to papers in which such a statement is made. Starting with that supposition, the writer was surprised to find that such was not the case, but that in most instances rancidity sets in and continues for some time without the liberation of any free acid whatever, and in others the development of free acid commences long before rancidity. Thus, it is found that with olive, rape, castor, and arachis oils, no increase of free acid whatever has taken place during the six months, even in the quantities shaken up every morning and allowed to stand in direct sunlight, while rancidity has commenced in the latter quantities. It is therefore unnecessary to mention the figures for free acid obtained every month in these oils, although, of course, it is certain that decomposition and liberation of free acid will take place after a certain prolonged exposure.

On the other hand, cotton seed and linseed oils develop free acid before rancidity sets in. Thus, the cotton seed oil in experiment A. became rancid shortly after the fourth month, whereas the free acid increased regularly from the beginning of the experiment at the rate of 0.08 per cent. per month (that being 30 per cent. of the total free acid), and amounted to 0.77 per cent. at the end of six months. In quantities B. and C. the free acidity rose to 0.45 per cent., while in D., E., and F. there was no increase, owing to the absence of light. Linseed oil affords results analogous to those of cotton seed oil: the free acid originally was 0.76

per cent., while at the end of half a year it had increased to 1.10, 0.91 and 0.81 per cent. in series A., C., and B. respectively.

2.—Potash Neutralising Power.

This was determined regularly once a month, but in no case was it found to be affected.

3.—Colour.

The quantities exposed to both sunlight and air (A. and B.) were rapidly bleached, castor, rape, arachis, and linseed becoming only faintly yellow, and cotton seed almost perfectly colourless. Olive oil gradually developed from a strong yellowish brown into bright pale green, and then faded until it became colourless.

The rapidity of the bleaching process seems to vary in different olive oils, as in olive No. 2, mentioned below and in Table I., the colour at the end of five months is only somewhat less yellowish-green than the original oil, whereas at the same period olive No. 1 had become bright green.

Quantities C., kept corked in direct sunlight, were slightly bleached, while the series kept in the dark were not at all affected, thus showing that light and air are both necessary to bleach or alter the colour of an oil.

4. Specific Gravity.

It was found that the specific gravities were affected to a very remarkable extent by exposure. Table II. embodies the results of determining every month the specific gravities at 15.5 C. of quantities A. (exposed to direct sunlight, uncorked, and agitated every morning) and C. (exposed to direct sunlight in a corked bottle).

TABLE II.—SPECIFIC GRAVITIES AT 15.5 C.

Set.	Name of Oil.	Original.	One Month.	Two Months.	Three Months.	Four Months.	Five Months.	Six Months.
A	Olive.....	916.8	918.7	919.3	920.8	921.5	922.7	924.6
	Castor.....	967.9	968.1	969.1	970.0	970.0	968.5	968.3
	Rape (colza).....	916.8	918.3	917.2	918.5	918.4	920.0	920.7
	Cotton seed.....	922.5	923.7	924.1	926.1	927.8	930.4	932.0
	Arachis (nut).....	920.9	921.3	922.1	923.3	923.9	925.6	926.7
	Linseed.....	932.5	933.1	933.6	935.3	935.9	937.2	938.5
C	Olive.....	916.8	917.5	917.4	918.1	917.3	917.2	918.5
	Castor.....	967.9	968.9	968.5			Discontinued.	
	Rape (colza).....	916.8	917.1	916.5	917.0	916.7	916.3	917.1
	Cotton seed.....	922.5	923.5	922.6	923.4	923.1	922.9	923.6
	Arachis (nut).....	920.9	920.9	920.8	920.9	920.9	920.9	921.6
	Linseed.....	932.5	932.4	932.6	932.6	932.8	932.6	932.7

In A. we find that olive oil increased in density from 916·8 to 924·6, castor from 967·9 to 968·3, rape from 916·8 to 920·7, cotton seed from 922·5 to 932, arachis from 920·9 to 926·7, and linseed from 932·5 to 938·5 in six months. None of the oils was rancid till the fourth month. Series B., which corresponds with ordinary samples left in sunlight imperfectly corked, showed an increase in specific gravity to 920·3, 968·0, 919·4, 925·9, 924·0 and 936·2 in olive, castor, rape, cotton seed, arachis, and linseed oils respectively. In set C., Table II., we find that some of the densities are affected to a noteworthy extent, but this change is apparently due chiefly, if not wholly, to slightly imperfect corking of the bottles, and the unavoidable admission of fresh air on the occasions when the periodical tests were performed.

Owing to these extraordinary and unexpected results, a large quantity of an entirely different olive oil (containing 11·28 per cent. of free acid as compared with 5·19 per cent. in the first-mentioned specimen) was exposed under the conditions marked A., C., and F., and hitherto has shown results in accordance with those above, having increased in four months from 916·5 to 919·0 sp. gr.

It will be noticed that the increase in density of the oils is by no means regular, month by month. This irregularity is due to a combination of many causes, the most important one being undoubtedly the weather—the temperature and the quantity of sunshine. That the rise in gravity is not due to mere contraction of the oils was proven by exposing quantities of olive oil in tall bottles, and noting the volume of the oil, at the same temperature, before and after exposure; it was not found to have varied.

On examining these figures, one is at once struck by the remarkable fact that the specific gravity is not necessarily a criterion of the purity of an oil, at least as the test is usually applied. For instance, one might obtain for analysis a sample of olive oil of professed purity, which on examination showed a density of 920·8, but was not in the slightest degree rancid, and from its colour and taste appeared to be simply a fine quality of olive oil. Could an analyst, in the present state of affairs, conscientiously certify such an oil to be genuine? He would probably believe that the sample was adulterated with some oil which he could not detect, and as our “constants” at present stand, he would be quite correct in taking that view. Yet such a case, and even a more remarkable one, could quite readily exist, as is shown by the above results.

Several other interesting peculiarities have been noted regarding the particular oils. It will be seen from Table II. A. that castor oil was the least affected of any by subjection to light and air, and after having increased in density during the first two months, gradually returned to almost its original gravity. In E. and F. (the quantities kept at rest in the dark, the latter securely corked), the specific gravity has fallen to 967·0. This last peculiarity, the depression of gravity in the series kept in the dark, has also been noticed in the cases of rape, earth-nut, and linseed oils. The following shows the fall in density after six months' treatment:—

—	Original.	D.	E.	F.
Rape	916·8	916·1	916·2	916·0
Arachis	920·9	920·3	919·9	920·0
Linseed	932·5	932·4	931·8	931·9

It is a striking fact that linseed oil, kept in the dark, exposed freely to the air, and even shaken up every morning, has not increased in density, but has rather diminished. In Allen's “Commercial Organic Analysis,” Vol. II., p. 120, we find the statement that in the absorption by linseed oil of oxygen from the air, “the action of light is not essential,” but that “in the dark, the chemical change is induced very slowly, but when once begun, it proceeds very rapidly.” The results yielded by the above experiments seem to show that the action of light is essential in bringing about the chemical change, as the quantity of oil was small, and had every opportunity for absorbing oxygen.

The only oil which increased in density by exposure to air in the dark was cotton-seed oil, which originally had a specific gravity of 922·5, the figures for the individual experiments being — for D. 923·3 and for E. 923·2. Quantity F. was unaltered.

5. Iodine Absorption.

Table III. contains particulars of the iodine absorptions of quantities A. and C., as determined month by month. In series A. no alterations of iodine equivalent beyond the limit of experimental error were observed during the first two months, and so, unfortunately, most of the tests were omitted during the next two months.

TABLE III.—IODINE ABSORPTIONS, PER CENT.

Set.	Name of Oil.	Original.	One Month.	Two Months.	Three Months.	Four Months.	Five Months.	Six Months.
A.	Olive	83·16	82·53	82·33	81·59*	..	79·13	78·24
	Castor	83·63	83·90	83·59	83·63	83·27
	Rape	105·59	105·90	105·90	..	103·45	102·21	102·13
	Cotton seed	106·84	107·47	107·16	106·17*	..	102·21	100·12
	Arachis	98·67	98·36	98·67	..	96·35*	95·40	93·20
	Linseed	173·46	171·78	171·78	169·07	166·17
C.	Olive	83·16	83·16	82·65	82·39	82·64
	Castor	83·63	83·90	83·27	..	Discontinued.
	Rape	105·59	106·21	105·90	..	105·02	..	105·27
	Cotton seed	106·84	107·78	108·41	106·65	106·90	107·79	106·40
	Arachis	98·67	98·67	98·67	99·12	97·60
	Linseed	173·46	173·04	172·63	172·88

[* The three figures marked with an asterisk in the table are obtained from the results given by quantities B. Thus, arachis oil, quantity B, gave a specific gravity of 924·0 and an iodine equivalent of 96·35 per cent. after six months' exposure. This gravity corresponds very closely with that of quantity A. at the fourth month, so that the iodine absorption may fairly be stated in Table III. as 96·35 per cent. Quantity B. of the cotton seed oil gave a density of 925·9 and an iodine equivalent of 106·17 per cent. This corresponds with the gravity of 926·1 given by A. at the third month.]

From the figures given it will be seen that for some time the halogen absorption is almost unaffected by the exposure to light and air; then a sudden break seems to occur,

probably at the third month, at which the absorption suffers a depression, after which it continues rapidly to fall. This point of change in the iodine number takes place a month

before the oil becomes rancid; in most cases much longer. Of quantities B., under the same conditions as A., only undisturbed, the results corroborate those in the table, but of course the depression has not gone so far. The only oil which has not decreased in iodine absorption is castor oil, which is thus exceptional both in regard to specific gravity and iodine number. It will be observed from the results at C., Table III., and those mentioned below, that in nearly every case both air and light are necessary to cause this change in iodine absorption, just as is the case with the density. There is, however, no numerical correspondence between the changes which take place in the gravity and in the iodine equivalent.

The quantities of the oils kept in the dark have in almost every case shown a very slight increase in iodine number. Rape oil, however, is an exception, and it is the only oil whose iodine equivalent has decreased independently of the action of light. Experiment D., at the end of six months, showed an absorption of 101.17 per cent., and quantity E. absorbed 101.49 per cent. The original oil, kept corked in the dark, was not altered.

6. Mauméné's Temperature Test.

Archbutt has recorded the fact that when olive oil is exposed to light for some time, the temperature reaction with sulphuric acid is increased to a considerable extent; to an extent, indeed, beyond the limits allowed to genuine olive oils. The figures he gives are:—Rise of temperature in oil kept in dark, 41.5° C., ditto in portion exposed to light, 52.5° C. Unfortunately, no mention is made of whether air was permitted to act on the oil exposed to light, nor of the duration nor circumstances of the exposure. In order to determine these points, and also to ascertain if the results yielded by olive form a general rule as to the behaviour of other oils, the rise of temperature was estimated in quantities A., C., D., and E. of all the oils after six months' exposure. As the results obtained were merely intended for comparison among themselves, ordinary concentrated sulphuric acid was used without any regard to its strength. Otherwise the tests were performed under the conditions mentioned in Allen's "Commercial Organic Analysis," Vol. II., p. 53, the highest temperature reached during the stirring being noted as the rise of temperature.

The results obtained are embodied in Table IV.

TABLE IV.—TEMPERATURE REACTIONS.

Set.	Olive.	Castor.	Rape.	Cotton seed.	Arachis.	Linseed.
	° C.	° C.	° C.	° C.	° C.	° C.
A.	67	78.5	72.5	100	90	131
C.	47	74.5	63	79.5	77	120
D.	43.5	73	60.5	76.5	73.5	112.5
E.	44	73	61.5	75.5	73.5	113.5

Series F., having been kept corked in the dark, may be assumed to represent the original genuine oils. As was to be expected, in every case has the remarkable increased rise of temperature been noted, but it has also to be observed that, except perhaps in the case of linseed oil, this change is not brought about by sunlight alone, as would be inferred from the foot-note in Allen, Vol. II., p. 99. Neither is it produced by the sole action of air, but by the combined action of both air and sunlight. This latter fact brings the change in temperature reaction on to the same footing as the alterations in colour, density and iodine equivalent. The slightly increased rise of temperature in series C. is in all probability due to the same cause as the similar elevation of specific gravity in the same quantities, namely, the admission of fresh air on the occasions when the oils were examined. It would appear that linseed oil, however, is affected by light alone, although not to such an extent as by the simultaneous action of light and air.

An examination of these temperature reactions in Table IV., in conjunction with the specific gravities in Table II., raises some very important questions. It will be observed that the rise of temperature varies directly as the density—the greater the increase in gravity, the greater the increase in temperature reaction—and therefore if an oil be placed under circumstances favourable to the raising of its specific gravity, it will also be likely to suffer a rise in temperature reaction. Now the temperature test is pretty generally adopted as a standard for the purity of olive oils, as few oils of importance have so low a temperature reaction, the limits permitted (allowing for the variation in results obtained by different methods) being from 39° to 45° C. Taking the case mentioned under "specific gravity" of an olive oil having a density of 920.8, the rise of temperature with sulphuric acid would at least be as high as 55° C., and these two data would in all probability be taken as almost conclusive proof of sophistication of the oil.

In analysing olive oils that have been stored for a long time in order to become acid for use in dyeing, the validity of the temperature reaction and specific gravity as tests becomes a very important matter. For instance, an undoubtedly genuine olive oil for dyeing purposes, containing 9.67 per cent. of free acid, which some time ago had a specific gravity of 915.4, and has lain for a few months in occasional diffused sunlight in a corked bottle containing a large quantity of air, has now a density of 918.6, and gives a rise in temperature of 53° C. The iodine equivalent is low—78.9 per cent., probably having decreased owing to exposure, as in Table III.—and the colour is bright green, the taste and smell being very faintly rancid. Another specimen of Gioja olive oil, which has lain under the same conditions, has a specific gravity of 916.6, iodine absorption 79 per cent., free acid 9.42 per cent. and temperature reaction 49° C. The colour of this sample is deep green, the taste and smell being quite sweet. Evidently in such cases Mauméné's test and the specific gravity are not reliable criteria, and even the iodine equivalent may be misleading if the original oil had already a low halogen absorption.

7.—Special Tests.

It was found on applying the élaudin test to olive oil, that the solidification of the mixture did not differ in quantities F. and D., both of which were kept in the dark. Quantity C. also yielded a solid élaudin, although not quite so hard as those given by F. and D. Experiment A., however, which had been subjected to the simultaneous action of light and air, showed no tendency even to thicken, when submitted to the élaudin test.

The efficiency of Bech's test was impaired to an exceedingly great extent in the quantity of cotton-seed oil exposed to both light and air. Experiment F., by Pattinson's modification of the test, gave a black precipitate and colouration, whereas quantity A. only imparted a light brown colour to the solution.

The conclusions arrived at from these experiments are, that the indications of the specific gravity must not be too readily accepted in cases where they point to the falsification of an oil. Neither should Mauméné's test be relied on implicitly, and, indeed, where the gravity of the sample under examination and the rise of temperature are abnormally high, and no clue can be discovered as to the supposed adulteration, these two tests, taken conjointly, should be considered as showing that the oil is an old one, or has been subjected to the conditions mentioned above. Even a very low iodine equivalent should not have much reliance placed upon it, unless the free acid and other tests show the oil to be fresh, and some satisfactory indications of adulteration are obtained. Apparently, however, the iodine absorption is the test which should be most depended upon, as it is the least liable to alteration of all the tests examined (except the potash neutralising power), and it only varies when radical changes have already taken place in density, &c.

ADDENDUM.

The temperature of turbidity in Valenta's test has been lowered by several degrees in quantities A. and B. of all the oils examined.

The following shows the change in the viscosity of rape oil. Quantity B., now exposed for 9 months, was tested along with quantity F.:—

	F.	B.
Time of flow at 15.5° C., in seconds	56	66
Time of flow at 50° C., in seconds	25.5	26.5

DISCUSSION.

Mr. R. R. TATLOCK said that, if he understood aright, the principal feature of the paper was that most seed oils were affected when exposed to air and light, and that the tests upon which they had been taught to rely for the analysis of these oils were no longer trustworthy. Mr. Ballantyne's experiments went to prove that when samples of oils were exposed, the density and specific gravity were much affected, and went on increasing according to exposure. Whether that was due to oxidation or not had not come out clearly, but they might assume for the present that it was so. The iodine equivalent was also affected after some considerable exposure, while the saponification was affected least of all. The days were—and not long ago—when the trustworthy chemical examination of an oil was almost an impossibility. They had then been taught to rely upon certain constants, as they are termed, particularly upon the iodine equivalent, and several others of a similar character, for the examination of these oils; and now Mr. Ballantyne rudely awakened them by saying that these oils may be subject, in keeping, to such alterations as would interfere with the constants. This showed how careful they ought to be before coming to any decision as to the examination of oils. The whole question was beset with difficulties. One question he would like to ask with reference to the nature of the change which took place was, did Mr. Ballantyne observe any increase in the weight of the entire sample operated upon which would point to oxidation of the oil, or whether an oil that had been so changed could be examined with results which would tell whether it was originally of a different character?

Mr. BALLANTYNE, in reply, said that, as indicated in his paper, there was no increase in the total bulk, but that, from the fact that the specific gravity had increased, he inferred that there was an increase in the total weight. Regarding the other part of the question, he was sorry that his experiments had not gone far enough to enable him to answer it.

Square. Being engaged as Lecturer by the Gilechrist Trustees, he undertook the duties of this post, and threw into the work all the energy of an earnest and strong nature. For many sessions Mr. Lant Carpenter greatly distinguished himself as a most effective lecturer under the Gilechrist Trust, especially in the North of England and in Scotland. At Bristol he was engaged in philanthropic work under the auspices of Miss Mary Carpenter, his aunt, and during the greater part of his residence in Bristol he took a pronounced part as its secretary in the management of the Boys' Industrial School there. He frequently lectured at the Philosophical Institution in Bristol, was an active member of the Naturalists' Society, and much interested in the foundation of the University College, Bristol, on the Council of which he represented the University of London.

Thus he was led to take an interest in the education question generally, and of late years the working of the Education Acts and the importance of Continuation Schools and Recreative Evening Classes have engaged much of his attention. He was local secretary at the Bristol (1875) meeting of the British Association, and may truly be said to have taken a leading part in all movements for the promotion of science, and especially physical science, in the West of England, where he was well known as a lecturer on such subjects. He was in charge of the chemical and part of the physical investigations of the deep-sea explorations of H.M.S. "Porcupine" of 1869 and 1870, his report on which was printed in the *Proceedings* of the Royal Society. William Lant Carpenter, besides being a member of the Institution of Electrical Engineers, was a Fellow of the Chemical Society and of the Physical Society. During the last ten years of continuous work his health had suffered a severe strain and a holiday became necessary. This was taken in 1889, but, combined with a journey to look after the schools on the Indian reserves in the Dominion of Canada for the New England Company, the journey became a strain instead of a rest, very few nights of his absence from home not being occupied in travel, so as to economise time. His health broke down again early in 1890, and so a voyage was undertaken to Australia and New Zealand, which he had visited in 1880 in order to seek restoration from the results of a similar collapse. Unfortunately no good effects followed from this voyage, though subsequently at Shanklin and Bournemouth some improvement was apparent, and his friends began to entertain hopes of his ultimate recovery. These were, however, doomed never to be fulfilled, and he died on December 23rd, leaving his four children, his brothers, and a wide circle of friends to mourn his loss.

With regard to Mr. Carpenter's publications, his excellent little book, compiled from his Gilechrist lectures, entitled "Energy in Nature," cannot be forgotten or overlooked, but since the once well-known, if not classic work on the Manufacture of Soap, by Morfit, no treatise on the Chemistry and Manufacture of Soap has appeared which can be considered equal to Carpenter's work entitled "Soap, Candles, Lubricants, and Glycerin," published by E. F. and N. Spon in 1885. Mr. Carpenter had also acted as examiner in the subject of Soap Manufacture for several years for the City and Guilds of London Institute. So solicitous was he not only for the condensation of the abstracts of English patents on the subject of Fats, Oils, and Soaps, appearing in the *Journal of the Society of Chemical Industry*, but that in such condensation adequate information should be given, that for several years, in addition to the heavy load of duty he had already taken on his shoulders, he undertook the abstracting himself of all patents bearing upon his favourite subject, and was always most punctual and prompt in the delivery of the MSS. In this earnest devotion to the part he had voluntarily undertaken to play both as member of Publication Committee and as abstractor, he thus followed closely in the steps of his distinguished and singularly devoted predecessor, Mr. Walter Weldon.

Obituary.

WILLIAM LANT CARPENTER, B.A., B.Sc. Lond., F.C.S., GILCHRIST LECTURER, FELLOW OF THE PHYSICAL SOCIETY, MEMBER OF THE SOCIETY OF CHEMICAL INDUSTRY, AND OF THE PUBLICATION COMMITTEE OF ITS JOURNAL, &c.

WILLIAM LANT CARPENTER was the eldest son of the late Dr. W. B. Carpenter, C.B., F.R.S. He was born in the year 1841 at Bristol, but was educated in University College School, London, and studied chemistry under Prof. Williamson in University College, London, and also in the Birkbeck Laboratory. He was, in 1859, engaged in the Broad Plain Soap Works, the proprietors of which were Messrs. Ch. Thomas Brothers, where, for nearly 20 years, he was a partner of the firm. At the termination of this partnership in 1881, Mr. Carpenter removed to London, and in 1882 he became connected with the School of Electrical Engineering in Hanover

Journal and Patent Literature.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

Non-conductors for Steam Pipes. Eng. and Mining J. 1890, 50, 650.

In order to show the relative merits of the different substances which are offered for preventing the escape of heat from boilers and steam pipes, or as substitutes for wire lathing and plastering, or for tin plates in the protection of elevator shafts, or of woodwork nailed closely to walls, the following tables are submitted. These tables and extracts are taken from a report made by Prof. Ordway, late of the Massachusetts Institute of Technology. It will be observed that several of the incombustible materials are nearly as efficient as wool, cotton, and feathers, with which they may be compared in the following table. The materials which may be considered wholly free from the danger of being carbonised or ignited by slow contact with pipes or boilers are denoted by a (†). Those which are more or less liable to be carbonised are denoted by a (*).

Ordway's report is as follows:—"Careful experiments have been made with various non-conductors, each used in a mass one inch thick placed on a flat surface of iron kept heated by steam to 310° F. The following table gives the amount of heat transmitted per hour through each kind of non-conductor one inch thick, reckoned in pounds of water heated 10° F., the unit of area being one square foot of covering.

Substance 1 in. thick. Heat applied, 310° F.	Pounds of Water Heated 10° F. per Hour through 1 sq. ft.	Solid Matter in 1 sq. ft. 1 in. thick. Parts in 1,000.	Air included. Parts in 1,000.
*1. Loose wool.....	8.1	56	944
*2. Live geese feathers.....	9.6	50	950
*3. Carded cotton.....	10.4	20	980
*4. Hair felt.....	10.3	185	815
*5. Loose lamp black.....	9.8	56	944
*6. Compressed lamp black.....	10.6	244	756
*7. Cork charcoal.....	11.9	53	947
*8. White pine charcoal....	13.9	119	881
*9. Anthracite coal powder.....	35.7	506	494
†10. Loose calcined magnesin.....	12.4	23	977
†11. Compressed calcined magnesin.....	12.6	285	715
†12. Light carbonate of magnesin.....	13.7	60	940
†13. Compressed carbonate of magnesin.....	15.4	150	850
†14. Loose fossil meal.....	14.5	60	940
†15. Crowded fossil meal....	15.7	112	888
†16. Ground chalk (Paris white).....	20.6	253	747

†18. Fine asbestos.....	49.0	81	919
†19. Air alone.....	48.0	0	1,000
†20. Sand.....	62.1	520	471

"The first column of figures of results, therefore, gives the loss by the measure of pounds of water heated 10°. The second column gives the amount of solid matter in the mass one inch thick. The third column gives the amount of bulk of included or entrapped air."

There are some mixtures of two materials which may be quite safe, although consisting in part of substances which may be carbonised. It must also be considered that a covering for a steam pipe or boiler should have some strength or elasticity, so that when even put on loosely and holding a great deal of entrapped air it may not be converted into a solid condition by the constant jar of the building, then becoming rather a quick conductor. This warning may be applied especially to what is called "slag-wool," which consists of short, very fine threads of a brittle kind of glass. The following table, giving the figures on which the graphical table is based, has been submitted by Ordway, with the following explanation:—

"The substances given in the following table were actually tried as coverings for 2-inch steam pipe, but, for convenience of comparison, the results have been reduced by calculation to the same terms as in the foregoing table:—

Covering.	Pounds of Water Heated 10° F. per Hour by 1 sq. ft.
*21. Best slag wool.....	13.0
*22. Paper.....	14.0
*23. Blotting paper wound tight.....	21.0
*24. Asbestos paper wound tight.....	21.7
*25. Cork strips bound on.....	14.6
*26. Straw rope wound spirally.....	18.0
*27. Loose rice chaff.....	18.7
*28. Paste of fossil meal with hair.....	16.7
*29. Paste of fossil meal with asbestos.....	22.0
*30. Loose bituminous coal ashes.....	21.0
*31. Loose anthracite coal ashes.....	27.0
*32. Paste of clay and vegetable fibre.....	30.9

"Later experiments, not yet published, have given results for still air which differ little from those of Nos. 3, 4, and 6. In fact, the bulk of matter in the best non-conductors is relatively too small to have any specific effect, except to entrap the air and keep it stagnant. These substances keep the air still by virtue of the roughness of their fibres or particles. The asbestos of 18 had smooth fibres, which could not prevent the air from moving about. Later trials with an asbestos of exceedingly fine fibre have made a somewhat better showing, but asbestos is really one of the poorest non-conductors. By reason of its fibrous character, it may be used advantageously to hold together other incombustible substances, but the less the better. Trials were made of two samples of a 'magnesia covering,' consisting of carbonate of magnesin with a small percentage of good asbestos fibre. One transmitted heat which, reduced to the terms of the first of the above tables, would amount to 15 lb., the denser one gave 20 lb. The former contained $\frac{2.50}{100.0}$ of solid matter; the latter $\frac{3.66}{100.0}$.

Charcoal, lamp-black, and anthracite coal are virtually the same substance, and Nos. 5, 6, 7, 8, and 9 show that

† Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d.	4d.
Above 8d., and not exceeding 1s. 6d.	1d.
" 1s. 6d., " " " 2s. 4d.	14d.
" 2s. 4d., " " " 3s. 4d.	2d.

non-conducting power is determined far less by the substance itself than by its mechanical texture. In some cases when a greater quantity of a material is crowded into the same thickness the non-conducting virtue is somewhat increased, because the included air is thereby rendered more completely fixed. But if the same quantity is compressed so as to diminish its thickness its efficiency is lessened; for the resistance to the transmission of heat is nearly, though by no means exactly, in proportion to the thickness of the non-conductor. Hence, though a great many layers of paper, as in No. 23, prove to be a tolerably good retainer of heat, one or two layers are of exceedingly little service. Any suitable substance which is used to prevent the escape of steam heat should not be less than an inch thick.

"Any covering should be kept perfectly dry, for not only is water a good carrier of heat, but it was found in trials made, that still water conducts heat about eight times as rapidly as still air."

A Novel Form of Flexible Tubing. T. R. Almond,
Eng. and Mining J. 1890, 50, 651.

THE author has made metallic flexible tubing that will convey gases, steam, or liquids under considerable pressure.

When a tube is formed by coiling a wire around a mandrel, the convolutions may be made to press upon each other with considerable force, and the joint formed at the point of contact of the individual convolutions will be tight in proportion to the amount of pressure exerted. If such a tube be bent, the joints will be broken all around the coils except at one point, and therefore, when bent, it is useless for conveying liquids or gases.

Wishing to utilise the peculiar flexibility of spiral spring tubing for the conveyance of gases in cases where a flexible tube is required, the author conceived the idea of interposing a triangular-shaped wire between the coils of a round wire. When a tube so constructed is bent, the convolutions of the triangular coil adjust themselves to the spaces between the round coils, as shown in Fig. 1. The triangular wire is pressed between the coils of the round wire during the process of constructing the tube with sufficient force to spread them apart, so that the contact surfaces are at all times under pressure. The triangular wire serves two purposes: one is to spread the coils apart, so that the pressure will be exerted on the contact surfaces; the other to fill the irregularly-shaped spaces between the coils of round wire, adjusting itself to the changing form of the spaces due to any given flexion. This pressure brings into play the element of friction to such an extent as partly to destroy the flexibility of the tube, which, when bent, will retain the form given to it.

As the primary object was to obtain a flexible tube, trials were made with wire having a more obtuse angle; such is shown in Fig. 2. This gave better results, as a more perfect joint was produced with less tension of the inner coil, and the friction became correspondingly less, the result being a tight tube with sufficient flexibility. Fig. 3 shows the shape of the seats into which the round wires are forced by their tension. The seat for the inner wire is much more obtuse, and on this account the inner wire will not, under a given tension, be forced into such a seat so tightly as in the sharper V in Fig. 3. It will be seen that the degree of flexibility depends upon the amount of tension put upon the inner coil, or the extent to which the convolutions are forced apart. The author has produced a perfectly tight tube with two coils of round wire, in which the outer coil is wound sufficiently tight between the convolutions of the inner coil to spread them apart for the purpose of getting pressure on the joints, substantially the same as with the triangular wire. This makes a very strong tube, but is too bulky for many purposes. Two half-round wires, or even less than half-round, may be used; or the inner wire may be round and the outer half-round, or much less than half-round. The tube will then be less bulky, and, supposing the outer wire to be considerably less than half-round, the convexity of its surface may be such as to give results similar to the obtuse triangular wire shown in Fig. 2. He has made several tubes

in which the contact surfaces of the coils are made to coincide with a circle whose centre is the axis of the tube. The joints so formed are practically a series of ball and socket joints; such a tube has smoother outer and inner

Fig. 1.

Fig. 3.

Fig. 2.

Fig. 4.

TYPES OF FLEXIBLE TUBING.

surfaces than those previously described. A serious objection to such a tube is that the wire changes its shape during the process of coiling, so that the joint surfaces will not make sufficiently complete contact, whereas the forms of wire previously mentioned are of simple construction, and the slight change of form which occurs during the process of coiling will not affect the result. The extent to which this tubing may be bent without leakage is considerable; a piece of $\frac{1}{4}$ -in. bore, tied as shown in Fig. 4, has been subjected to a steam pressure of 75 lb. without leakage. The smallest curves of the bent portion corresponded in this case to a circle 2 in. in diameter. The author has not yet made any tube larger than $\frac{5}{16}$ -in. bore, but thinks it possible to make them as large as 1-in. bore, and strong enough to stand any ordinary steam pressure. For purposes where pressure is not required, the tube may be made of sheet metal, and may possibly be made as large as 2 in. in diameter.

PATENTS.

Apparatus for the Purification of Lubricating and other Oil. J. Deuss, Gladbach, Germany. Eng. Pat. 13,324, August 23, 1889. 6d.

THE purpose of this invention is the purification of oil which has been used for lubricating machinery, in order that it may be used again. This is effected by means of a filter which is described and illustrated in the specification.

Improved Means or Apparatus for Withdrawing Molten Glass or Molten Metals from Furnaces, and Controlling the Outflow thereof: also applicable for Conveying Liquids or Chemicals of a Liquid Nature from Larger to Smaller Vessels or Receptacles. D. Rylands and J. W. Horner, Barnsley. Eng. Pat. 17,933, November 11, 1889. 8d.

This invention consists in the combination of a syphon pipe and controlling vessel raised and lowered by any suitable mechanical means, for withdrawing and controlling the outflow of molten glass and molten metal from furnaces with air-ejecting arrangements and firing appliances.

—E. G. C.

An Improved Method of and Means for Purifying the Waste or Impure Matters from Tanneries, Factories, Dye-works, or similar or other Sources. J. W. Calvert and J. Chaffer, Leeds. Eng. Pat. 18,946, November 26, 1889. 6d.

The process consists in the precipitation by strong sulphuric acid and filtration of the resulting liquid through a filter bed which is described and claimed. The filtering materials are sawdust, broken stone and broken brick. The liquid is subjected to a preliminary settling in tanks, and the sludge removed for manure.—J. M. H. M.

Improved Apparatus for Filtering Sewage and other Liquids. W. Birch, Manchester. Eng. Pat. 4732, March 26, 1890. 8d.

See under XVIII. B., page 61.

An Improved Method of Drying and Desiccating Sludge, Manure, and other Materials. G. V. Haslam and P. Cornish, London. Eng. Pat. 11,747, July 26, 1890. 6d.

The material to be dried is fed into a hopper and thence is conveyed by "broken blade" screws through a series of open cylinders which are enclosed or arranged in a suitable furnace. The heat from the fire is conveyed first along under the cylinders and then back over the top surface. It is preferred to serrate the edges of the screw blades to complete the drying and desiccating. The specification is accompanied with suitable drawings.—V. H. V.

II.—FUEL, GAS, AND LIGHT.

On the Lighting of Paris. J. für Gasbeleuchtung, **33**, 551—553.

On the occasion of the international conference of electricians in Paris last spring, M. Hippolyte Fontaine reviewed the various methods of illumination employed since the establishment of the great Paris Gas Co. (*i.e.*, during the last 30 years). The address dealt with the various illuminating agents under the following heads:—

I. *Wax, Tallow, Stearin, &c., in Candles.*—The following table gives the amounts of tallow and stearin products brought into Paris, as calculated from the Customs duties:—

Year.	Tallow.	Wax and Stearin.
	Kilos.	Kilos.
1855	1,299,572	1,288,213
1877	670,500	3,599,671
1889	307,880	1,115,263

In estimating amounts of light produced, the author adopts as the unit the so-called "decimal candle"; this is one-twentieth of the platinum light-unit adopted by the Congress of 1884, and corresponds to about 1/10 Carcel. This decimal candle requires a consumption of 8.5 grms. of wax per hour. 10 grms. would be a fairer estimate (taking an average for wax and tallow, and allowing for waste), and on this basis the following numbers are calculated:—

Year.	Number of Inhabitants.	Candle-hours per Inhabitant per Year.
1855	1,174,346	220
1877	2,044,819	210
1889	2,389,705	190

The use of candles has, therefore, remained fairly steady, but with a slight tendency towards decrease. It should be noticed that 30 years ago the amount of tallow used was equal to that of wax and stearin. The latter have increased in importance, whereas the consumption of tallow has steadily gone down.

II. *Vegetable and Animal Oils.*—These are calculated in the same way, and divided up as follows, according to their uses:—

Year.	For Food.	For Painting, &c.	For Lighting.
	Kilos.	Kilos.	Kilos.
1855	2,466,127	1,174,346	6,894,654
1877	4,294,182	2,044,819	7,871,721
1889	5,018,380	2,389,705	6,180,339

The illuminating power of the "decimal candle" above referred to would correspond to that of a good Carcel lamp burning 4.2 grms. per hour. 5 grms. per hour would be a more correct estimate for ordinary lamps. This gives a total of 1,236,067,800 candle-hours for the year 1889, or 517.2 candle-hours per inhabitant. The table shows that, before the introduction of petroleum, vegetable oils formed the most important artificial source of light. Now, however, their importance is rapidly diminishing.

III. *Petroleum and Petroleum Products.*—Mineral oils were first practically used for lighting in 1865. Since that time the use of petroleum has enormously increased. In a few years the amount of light produced by it has become 10 times as great as that from candles, and five times as great as that from vegetable oils. This is shown by the following table, which is calculated on the basis of 3.8 grms. of petroleum and 6 grms. of petroleum-naphtha per candle per hour (or an average of 4 grms.).

Year.	Petroleum and Naphtha used for Lighting.	Candle-hours per Inhabitant.
	Kilos.	
1872	3,759,556	503.1
1877	5,019,716	722.0
1889	19,084,664	1,995.0

The increased use of petroleum accounts for the smaller consumption of vegetable oils.

IV. *Gas* is the illuminant most commonly and largely used in Paris. Its production is a monopoly in the hands of the *Compagnie Parisienne du Gaz*. The price paid is 0.30 franc per cubic metre for private use, and 0.15 fr. per cubic metre for the town lighting. The company pays a duty of 0.02 fr. for every cubic metre of gas used in Paris, and 200,000 frs. for the use of the streets. It further has to give up to the town one-half of all profits above 10 per cent. (see end of abstract). The production of gas, expressed in

millions of cubic metres, was 40·8 in 1855, 191·2 in 1877, and 312·2 in 1889. In the latter year private consumption accounted for 159·9, and public lighting for 30·1, the rest being used for heating, &c. and outside Paris. The use of gas for heating purposes is rapidly increasing.

The following table is calculated on an average basis of 12·5 litres of gas per candle-hour. (The burners in common use consume about 14 litres per candle-hour. There are better burners, that only consume 5, 4, or even 3 litres, but they are not much used):—

Year.	Total Candle-hours.	Candle-hours per Inhabitant.
1855	2,781,000,000	2,371
1877	9,768,000,000	4,776
1889	15,200,000,000	6,470

Thus the consumption of gas does not diminish, in spite of the increased use of petroleum and electricity. The year 1889 was, however, an abnormal one. Under ordinary circumstances the last number would have been 6,080 instead of 6,470. In addition to the gas company's supply from the mains, some use is made of compressed gas of high illuminating power. This is made of a sort of boghead coal, and is supplied to the consumer in cylindrical holders, under a pressure of 10 to 12 atmospheres.

V. The *Electric Light* first appeared in Paris in 1873. In 1877 the Jablochhoff candle was introduced, and in that year Paris contained 22 electric light installations, employing 230 H.P. In 1883 the horse-power had risen to 900, giving a light of 360,000 candles. Between steam-engines, gas-engines, and other motors, there was, towards the end of 1889, in actual use a total of 17,400 H.P., supplying current for 6,800 arc lamps and 118,000 incandescent lamps. The total candle-power thus produced is 3,484,800, so that 1 H.P. is equivalent to about 200 candles. Assuming the lights to be run for four hours per day, this gives nearly 57 million candle-hours per year, or 2,130 candle-hours per inhabitant per year. About a third of this light is produced by means of arc lamps, which certainly do not consume more than 1 to 1·5 Watts per candle. Incandescent lamps have also been so much improved that they only require about 4 Watts per candle.

In addition to the above, there are now in construction central stations, having an aggregate of 10,600 H.P., and preparations are already being made for further installations amounting to at least 3,900 H.P. Thus one may expect to have 32,000 H.P. at work in 1891 or 1892. The following table for electric lighting is calculated on the assumption that the lamps have hitherto been run only four hours per day (a number which will certainly be exceeded in future):—

Year.	Candle-hours per Annum.	Candle-hours per Inhabitant per Annum.
1877	134,220,000	65
1883	525,560,000	230
1889	50,878,080,000	2,130

The above tables show that the total artificial illumination in Paris amounts to 11,300 candle-hours per inhabitant per year, or 30 per day. This is divided as follows: Wax, tallow, and stearin, 1·6 per cent.; vegetable oils, 4·5 per cent.; petroleum, 17·7 per cent.; electricity, 18·9 per cent.; gas, 57·3 per cent. II. Fontaine draws the following general conclusions: (1.) The present illumination in Paris is three times as great as it was 30 years ago. (2.) Vegetable oils, wax, stearin, and tallow only supply 6 per cent. of the total, and this quantity diminishes every year. (3.) The three most important illuminants are gas, electricity, and petroleum. The consumption of gas remains stationary, while that of petroleum is rapidly increasing. Although electricity is the newest competitor, it has already taken the second place.—D. E. J.

The following is taken from the "Electrician," Nov. 14, 1890:—

The concession granted to the Compagnie Parisienne du Gaz has recently (Nov. 10) been prolonged for a period extending from 1905 to 1930. The company is authorised to exploit any system of lighting and heating, including the electric light and other applications of electricity. The price of gas for lighting purposes is to be reduced from 0·30 fr. to 0·25 fr. per cubic metre (*i.e.*, from 7s. 6d. to 6s. 3d. per thousand), and from 0·30 fr. to 0·20 fr. in the case of gas-engines, &c.—D. E. J.

Zirconia as a Substitute for Lime in the Oxyhydrogen Light. W. Koehs. *Dingl. Polyt. J.* 278, 235—240.

THE high light-emitting power of zirconia has been observed by many experimenters, an historical account of whose labours occupies the first portion of this article. Now that compressed oxygen is cheap, and zirconia a fairly common article of commerce, many applications of a zirconia "lime light" working with ordinary coal gas are feasible. Linne-mann has devised a burner which, now it has been improved by Wolz, of Bonn, is well adapted for its purpose. The main points to be considered are: the use of oxygen at sufficient pressure to cause the combustion of the gases as they issue from the burner to take place about 0·5—1·0 cm. above its mouth in order to obtain a conical flame of the highest intensity which shall not overheat the burner itself, a result which is attained by supplying the oxygen at a pressure of about 15 times that of the coal gas. The complete and immediate consumption of the burning gases is so important a condition of success that large burners have not proved economical on account of the failure of the large central stream of oxygen to mix rapidly enough with the coal gas as it issues. This imperfection can be detected by observing the flame through a smoked glass, when the point at which unconsumed oxygen impinges on the incandescent zirconia can be recognised as a black spot. Even under these unfavourable conditions, but little disintegration of the zirconia takes place. The zirconias used by the author are as pure as possible, and made in the form of cylinders 2 × 0·8 cm., and yield a light of 40—50 candle power when heated with 30 litres of oxygen and 30 litres of coal gas per hour.

When a comparison of the light emitted by gas burned under different conditions is made, using an amyl acetate lamp as a standard, it is found that 30 litres of gas per hour simply burnt as it issues from a circular opening give only one candle power. The use of 30 litres of oxygen instead of air, and the introduction of a cylinder of zirconia increases the light therefore some forty-fold without augmenting the heat evolved in the least. The colour of the light is comparable with that of the electric arc.

The zirconia light as thus arranged readily lends itself to spectroscopic, photomicrographic, and medical use.—B. B.

PATENTS.

Improvements in Means for Generating and Utilising Gas or Vapour, and in Apparatus therefor. P. L. Girardet, jun., Constantine, Algeria. Eng. Pat. 16,393, October 17, 1889. 6d.

AN inverted metallic U-tube has the lower parts of its limbs plugged with cotton wool or asbestos, and immersed in a liquid hydrocarbon. Beneath the bend of the U-tube is placed a cotton-wick burner, supplied from the same reservoir as the U-tube. The heat from the wick-burner volatilises the hydrocarbon drawn up in the U-tube by capillary attraction, and the vapour produced escapes by a small tube inserted in the bend of the U-tube. The vapour, which may be mixed with air or not, according to circumstances, is led to a suitable burner and used for heating or lighting purposes.—H. K. T.

Improvements in Apparatus for the Manufacture of Illuminating Gas. F. J. Jones, St. Albans. Eng. Pat. 19,721, December 7, 1889. 8d.

This invention consists in heating coal in a stream of the gases resulting from the action of steam upon red-hot coke, the resulting mixture of gases and vapours being converted into permanent gas by passing them through a superheater. The apparatus consists of a water-gas producer, a series of retorts placed in a vertical or inclined position and a superheater, the whole being enclosed in a chamber heated by gaseous fuel. Sometimes the gas is enriched by injecting petroleum, tar, &c., into the superheater. In this case the superheater should be filled with coke, and should admit of the latter being changed from time to time to prevent choking by deposited carbon.—H. K. T.

An Improved Apparatus for Charging Inclined Gas Retorts. F. Morris, Brentford. Eng. Pat. 19,763, December 9, 1889. 6d.

This invention consists in separating retorts charged on the Y or λ plan into two separate retorts, each retort being closed by its own lid so that when one is being charged there is no danger from flame owing to the gas produced in the other.—H. K. T.

Improvements in the Method for Producing Intense Light by Magnesium or by other Glowing Materials. J. W. C. C. Schirm, Berlin, Germany. Eng. Pat. 11,784, July 28, 1890. 8d.

This is an apparatus consisting of a Bunsen burner, the inlet tube of which is fitted with a funnel-shaped vessel containing powdered magnesium, aluminium, or other substance capable of giving a glowing light. The powder as it falls through the aperture of the vessel into the pipe is carried along by the stream of coal-gas, and burns with an intense white light at the mouth of the burner. When an intermittent light is required an elastic ball is attached to the gas tube and becomes filled with gas. On violently compressing the ball the gas is delivered by means of a specially arranged valve to the burner, carrying with it a quantity of metallic powder previously introduced into the tube. An arrangement in which benzene vapour is used is also described.—H. K. T.

Improvements in Incandescent Gas Burners. C. S. Upton, New York, U.S.A. Eng. Pat. 15,463, September 30, 1890. 8d.

This invention consists of various forms of burner of the incandescent type in which a cap or thimble of platinum wire or other suitable material is raised to a white heat in a Bunsen flame. The burner consists of a metal chamber variously perforated so as to cause the issuing flame to impinge upon the refractory material. Air is conveyed to the lower part of the burner by means of tubes which also form supports for a shade and reflector.—H. K. T.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

The Cinnamenes (Styrol Compounds) of the Benzene Hydrocarbons and their Conversion into Anthracene and Methylated Anthracenes. G. Kraemer, A. Spilker, and P. Eberhardt. Ber. 23, 3260—3276.

The cinnamene (styrol) employed in this research was prepared from synthetic cinnamic acid, as its isolation from crude xylene was considered too difficult. For this purpose, 1 kilo. of cinnamic acid was subjected to a very

slow process of distillation, occupying between four and five hours for its completion. 360 grms. of crude cinnamene were obtained, and this, after purification by fractional distillation under reduced pressure and redistillation under the ordinary pressure, gave 320 grms. of pure cinnamene. Commercially pure xylene mixed with 5 per cent. of this product gave the same compound as that obtained from crude xylene. According to the formula previously given (Ber. 15, 3170), the substances formed by the above process of condensation are α - γ -substitution products of propane. In order to explain their conversion into anthracene derivatives it is necessary to assume the removal of a carbon atom from the middle of the molecule, the latter splitting up into two parts and then re-uniting. It is, however, hardly probable that so complicated a reaction would be accompanied by such high yields as are invariably obtained when these anthracene derivatives are formed. Pinner and Liebermann have recently illustrated the condensation in the following manner:—

α - β -propane derivatives being formed. In accordance with this view the production of anthracene is easily explained by the equation—

and as the authors consider this reaction feasible and highly probable, they have no hesitation in regarding the compounds described in the paper as α - β -derivatives.

Methods are given in detail for the preparation of *Meta-xylene cinnamene* or α - β -phenylmetatolylpropane—

Toluene cinnamene or α - β -diphenylpropane—

$C_6H_5 \cdot CH(CH_3) \cdot CH_2 \cdot C_6H_5$, and *Pseudocumene cinnamene* or α - β -phenyltolylpropane—

with descriptions of properties of these compounds.

Several unsuccessful attempts were made to combine benzene with cinnamene, a result which seems to show that the condensation cannot take place without the presence of a side chain (methyl group) which effects the combination.

The properties of the hydrocarbon obtained from cinnamene and toluene are consonant with the reactions of the α - β -diphenylpropane prepared by Silva (Compt. Rend. 89, 606) by the action of propylene dichloride on benzene, which boils at 277—279°, and of the α - γ -derivative described by Graebe (Ber. 7, 1627) and von Claus and Mercklin (Ber. 18, 2938) which boils at 290—300°. Graebe's compound was prepared from dibenzylketone by reduction and the diphenylpropane of von Claus and Mercklin by the action of triethyldryd on benzene in the presence of aluminium chloride.

The hydrocarbons $C_{14}H_{16}$ and $C_{16}H_{18}$ described by Weiler and Fischer (Ber. 7, 1181) are isomeric but not identical with the compounds obtained by the authors. These bodies also yield methylanthracene when their vapours are passed through red-hot tubes.—D. B.

On Indene and Cinnamene (Styrol) in Coal Tar. G. Kraemer and A. Spilker. Ber. 23, 3276—3283.

In a previous communication on the presence of coumarone in coal tar (this Journal, 1890, 275) the authors expressed the opinion that besides this hydrocarbon there are bodies similarly constituted in the fractions of high boiling point

obtained from light tar oils. The isolation of coumarone was effected by means of bromine, but the authors have since found that by forming the pierate the separation is performed with greater ease. The process is described in detail in a German patent (No. 53,792) which the authors have recently secured, and it is here only mentioned by way of addition that the melting point of the pierate is 102° – 103° .

Indene is obtained by saturating the fraction of the light tar oils boiling between 176° and 182° with pieric acid at an elevated temperature. On cooling, the pierate crystallises out. It contains some coumarone and all the naphthalene originally present in the tar oil, and is purified by distillation with steam. The distillate is then again treated with pieric acid in a solution of toluene. The resulting pierate forms golden yellow needles melting at 98° . It decomposes gradually on exposure to the air and is readily and completely split up by steam. 10 kilos. of the tar fraction gave 2 kilos. of indene. This is a colourless oil boiling at 177° – 178° ; under 757 mm. pressure it has a specific gravity of 1.040 at 15° , and its formula is C_9H_8 . The vapour density determination by V. Meyer's method gave 123 and 119 (theory = 116). It is resinified by concentrated sulphuric acid with formation of para-indene. In order to determine its constitution indene was subjected to the action of oxidising agents. Chromic acid and potassium permanganate gave unsatisfactory results; nitric acid, however, yielded an acid which proved to be orthophthalic acid. Hence, out of nine carbon atoms six are united in the form of a benzene ring to which simultaneously two other carbon atoms are attached in the ortho position, so that the constitution is represented by the formula—

Indene is, therefore, the fundamental hydrocarbon of hydrindene, indole, and indigo respectively. It combines with bromine, forming a dibromide, $C_9H_8Br_2$, which crystallises in colourless prisms melting at 43° – 45° , and dissolves in organic solvents. Water decomposes it into the hydroxy-bromide, C_9H_8BrO , with separation of hydrogen bromide. This product forms long white needles melting at 130° – 131° , and may also be obtained by saturating the original tar fraction with bromine in the cold, distilling the mixture with steam and extracting the bromide from the black resinous residue by means of water.

On reduction with sodium in an alcoholic solution indene is converted into hydrindene, C_9H_{10} . The latter has a specific gravity of 0.957 at 15° , and boils at 173.5° – 174.5° .

Although the presence of cinnamene in coal tar has been observed by Berthelot and others, the authors have recently isolated this hydrocarbon from the fraction boiling between 140° and 150° . The best results were obtained by the separation process with bromine owing to the fact that the pierate is very unstable and dissolves too readily in the light tar oil to admit of its crystallisation therefrom.

The discovery of indene fills up a gap in the list of substances found in coal tar to which reference has been made in the authors' paper on coumarone. Indene stands midway between fluorene and another product of dry distillation, which the authors are hopeful of finding in the lowest boiling fractions of the tar oils, or possibly in coal gas itself, thus—

In conclusion it is stated that it is the presence of indene more than that of coumarone which causes the colouration obtained with various tar products on treatment with concentrated sulphuric acid; the red colour, for instance, which impure naphthalene gives with sulphuric acid is due to the presence of indene, and doubtless also the colour which phenol produces.—D. B.

Turbidity in Mineral Oils. A. Veith. *Dingl. Polyt. J.* 277, 567–571.

MANY apparently well-refined samples of mineral oil, though at first quite clear and bright and neutral to the usual reagents, lose their limpidity after a while and become turbid and of a bad colour. Such oils burn badly and cause trouble both to the manufacturer and consumer.

The cause of these phenomena can only be made clear by a consideration of the nature and method of refining of the crude petroleum. Besides the hydrocarbons of the paraffin, paraffene, olefine, and naphthene series that constitute the bulk of the oil, certain less saturated organic substances are present. These, together with decomposition products, containing oxygen which form during the distillation of the crude material, render the process of purification as usually carried out necessary. The treatment with vitriol commonly adopted removes a portion of the more easily attackable hydrocarbons as sulphonic acids, and oxidises another portion of the impurities, a reaction indicated by the evolution of sulphur dioxide during the treatment. After separating the sulphuric acid laden with impurities, the remaining small quantity is removed by washing with caustic soda. The expenditure of these chemicals is cut down to the lowest limit by the manufacturer, whose interest here runs counter to that of the consumer, with the result that the cheaper kinds of oil are sometimes put on the market imperfectly refined. The turbidity already referred to makes its appearance in a highly characteristic manner. If one portion of the oil be exposed to sunlight in an open vessel no notable change occurs; another portion kept in cask becomes increasingly turbid. On exposing this turbid portion to light and air again it becomes perfectly clear again. When such a sample of mineral oil is treated with sulphuric acid of sp. gr. 1.5 it remains colourless, the acid becoming a light rose colour; on shaking with caustic soda of sp. gr. 1.2 it becomes dirty yellow or straw yellow in shade. The precise cause of the formation of the turbidity is not easy to ascertain. It was at first ascribed to the size used to make the casks tight, but it was proved that well-cleaned casks had the same effect. Shaking with water did not suffice to clarify the oil, but caustic soda was perfectly effective. Full elucidation of the question failed for want of opportunity, but it appeared probable that the turbidity might be due to the presence of sulphonates. On shaking the oil with magnesia which was afterwards dried and ignited, the presence of sulphuric acid was recognised by the ordinary tests. The existence of sulphonic acids was further proved by shaking out with caustic soda and precipitating the neutralised lye with barium chloride; the precipitate on ignition evolved combustible gases and left a residue of barium carbonate and sulphate.

Engler states (*Erdöl von Baku*) that mineral oil is treated in many Russian refineries direct with concentrated lye immediately after the acid in order to prevent the occurrence of this objectionable turbidity. Experimenting in this direction, a portion of the distillate before further refining was treated with caustic soda of sp. gr. 1.2, whereby the presence of organic acids which could not have resulted from any sulphonating action was proved. The same oil showed a greater proportion of organic acids after treatment with vitriol.

The sole practical means of preventing the turbidity or reducing it to a minimum is the use of caustic soda. The distillate from the refining still is treated with about 1 per cent. of caustic soda sp. gr. 1.3, and mixed intimately therewith. When separation from the tarry soda solution has taken place after some hours' standing, the oil is treated with sulphuric acid, thoroughly washed and again treated with a small quantity of strong lye. If a portion of the oil after allowing separation to take place be proved to suffer no further change on shaking with caustic soda sp. gr. 1.2, the bulk may be run off and well washed. Complete separation of the lye is necessary to prevent decomposition of the soda salts, formed by the action of the lye on the impurities of the oil by subsequent dilution.—B. B.

On the Condensation of Acetylene by the Silent Electric Discharge. M. Berthelot. Bull. Soc. Chim. (3), 4, 1890, 480—481.

ACETYLENE that has been condensed by the silent electric discharge forms a highly oxidisable product which in a few weeks absorbs more than a quarter of its weight of oxygen, a fact that has also been observed by Schutzenberger. The substance has the appearance of yellowish and resinous pellicles which undergo gradual and spontaneous change with the deposition of carbonaceous matter. When subjected to dry distillation the substance undergoes a sudden decomposition, leaving a considerable residue of carbon and liberating a very large quantity of water mixed with acetic acid and acetoneous liquids, analogous to those from sugar and tartaric acid. Neither benzene nor furfural is formed. Heated with soda-lime only acetone is formed. These observations show that the condensation of acetylene effected by the electric efluvium differs altogether from the condensation effected by heat, which at a temperature of from 400° to 500° C. chiefly results in the formation of benzene.

—H. S. P.

Asphaltum. Eng. and Mining J. 1891, 51, 13.

ASPHALTUM is found in the United States in California, Utah, Colorado, Wyoming, and at several places in the Southern States, but the only useful sources, at present, are the two States first named. In Utah hard varieties of the mineral are found in several widely-separated localities, in veins quite free from foreign substances, and of considerable size.

In 1888, 700 tons of asphaltum were shipped from Utah to St. Louis, and used for making varnish. Its value there was 35,000 dols. About 100 tons of ordinary asphaltum were produced in the territory the same year. In California, the product of liquid asphaltum, known as brea, from Los Angeles and Ventura counties, was estimated at 4,600,000 galls. This substance is of a glossy black colour, impervious to water, and particularly adapted for coating iron. It is used chiefly in the manufacture of paint and varnish, and the demand for it is increasing.

In 1888 the mining of sandstone or loose sand cemented by asphaltum became an important industry in California. The material mined is heated until soft, and in that condition laid as a pavement, for which purpose it is produced in large quantities, and eagerly sought. Of this material, in 1888, 13,000 tons were produced, valued at 5 dols. per ton, the total value of asphaltum produced in the United States in 1888 being 334,500 dols. In the year preceding, the production was 4,000 tons, valued at 16,000 dols.

ASPHALTUM PRODUCTION, IMPORTS AND EXPORTS, IN THE UNITED STATES.

Year.	Production.		Imports.*		Exports.*	
	Quantity.	Value.	Quantity.	Value.	Quantity.	Value.
1887	Tons. 4,000	Dols. 16,000	Tons. 27,523	Dols. 100,327	Tons. 203	Dols. 3,906
1888	53,800	331,560	10,673	113,854
1889	43,174	89,211
1890	78,391	180,555	258	3,965

* Fiscal years ending 30th June.

By far the most important deposits of asphaltum in California are those of Ventura county, which were discovered in 1888. This material differs from the substance found elsewhere in California in its large proportion of fixed carbon, and in that respect compares favourably with the well-known asphaltum of Val de Travers and Trinidad. The composition of the Ventura asphalt is

compared with that of other asphalts in the following table:—

Locality.	Fixed Carbon.	Volatile Carbon.	Residue.
Val de Travers.....	11'50	..	88'50
Ventura Co., Cal.....	24'40	..	75'60
Mendocino Co., Cal.....	1'70	11'60	86'70
Santa Cruz Co., Cal.....	2'58	18'16	79'26
Ditto ditto	1'90	13'54	84'56
Ditto ditto	7'56	46'20	46'24
Santa Barbara Co., Cal...	1'90	14'10	84'00
Ditto ditto ...	8'00	42'30	49'70
Los Angeles Co. (Brea)...	14'40	71'40	14'20

The composition of the Trinidad asphalt is extremely variable; the residue ranges from 30 to 60 per cent., and the bitumen (fixed and volatile) from 40 to 70 per cent.

The asphaltum of Ventura county, now being mined by the Ventura Asphalt Company, is stated to be an unusually hard and tough material. It begins to soften at 212° F.; becomes waxy at 248; begins to volatilise at 347°; but does not melt until 383°. Its tensile strength is from 600 to 700 lb. per square inch; and when mixed with 60 per cent. of sand, is from 821 to 825 lb. It is impervious to water, and unaffected by salt water or the atmosphere.

The principal use for asphaltum is in paving roads and in the construction of sea walls and other masonry work. Large quantities also are used in protecting wharf piles and timbers and the bottoms of boats.

Asphaltum can be produced, it is said, in large quantities from the Ventura mines; it is sold there on board cars at 9 dols. per ton.

The asphaltum used in the United States hitherto has been imported chiefly from Trinidad. With the large deposits now known in Utah and California, however, it is probable that the needs of many parts of the country will be supplied from domestic sources, and that the industry will grow rapidly.

IV.—COLOURING MATTERS AND DYES.

o-Methylbenzidine. R. Hirsch. Ber. 23, 3222—3226.

MOLECULAR weights of nitrobenzene and orthonitrotoluene dissolved in about five times the weight of alcohol, are reduced after addition of 10 per cent. of caustic soda with an excess of zinc dust. After boiling for several hours the colour of the solution and of the precipitate is grey or light yellow. The author thinks it however advisable to use an excess of *o*-nitrotoluene, about 4 parts to 1 part of nitrobenzene, thus avoiding the formation of benzidine, which can only be separated from methylbenzidine with great difficulty. The alcohol is distilled off after addition of water and the residue is carefully neutralised with hydrochloric acid after cooling, until all zinc oxide is dissolved. As soon as a filtered sample becomes cloudy on addition of sodium acetate the addition of hydrochloric acid is discontinued, and the zinc salt is separated by filtration from the insoluble hydrazobenzene and its homologues. They are then dissolved in hydrochloric acid, filtered, the excess of free acid neutralised and the bases precipitated as sulphates by means of sodium sulphate. The sulphates are converted into the free bases by sodium carbonate and the separation of the bases from each other effected by their different solubility in water.

Boiling water dissolves 1·05 per cent. of benzidine, 0·33 per cent. of tolidine.

Boiling water dissolves of mixtures of the two bases 1·1—1·3 per cent., but never so much of tolidine, as if the pure base had been used.

Water of 20° C. dissolves 0.04 per cent. of benzidine, 0.014 per cent. of tolidine.

When the mixture of the bases, obtained in the experiment described above, was boiled repeatedly with 50 times its weight of water, the quantity of the dissolved bases decreased and the remainder after the third boiling consisted of pure *o*-tolidine. The first solution contained after cooling 0.15 per cent., that is four times the quantity of benzidine soluble in water. The extractions by boiling of the base thus obtained were continued until the cold solution contained no more dissolved in it than could be found in a saturated benzidine solution. The united solutions were then precipitated by very careful addition of dilute sulphuric acid (an excess of acid has to be avoided as methylbenzidine-sulphate is more soluble in it than in water), the sulphate is reconverted into the base and the free base again boiled five times with 20 times the amount of water. The crystallisations from the two first solutions were pure *o*-methylbenzidine. It forms plates melting at 115° C.

The author prepared the acetyl- and benzylidene compounds by the action of acetic anhydride and benzaldehyde on the three bases. The following table shows their properties:—

	Benzidine.	Methylbenzidine.	Tolidine.
Diacetyl compound melts at.	317° C.	310° C.	306° C.
Diacetyl compound is soluble in.....	$\left\{ \begin{array}{l} 12 \text{ parts of} \\ \text{glacial} \\ \text{acetic} \\ \text{acid.} \end{array} \right\}$	6 parts.	6 parts.
Benzylidene compound melts at.....	227° C.	217° C.	140° C.
Benzylidene compound dries & tallises from alcohol.....	In cloudy flakes.	In yellow plates.	In long needles.

—A. L.

The Indigo Synthesis from Anilido-acetic Acid. A. Biedermann and R. Lepetit. Ber. 23, 3288—3291.

ONE molecule of aniline, well mixed with one molecule of monochloroacetic acid, is quickly heated with 3—4 times the quantity of caustic soda, until the mixture appears yellow and finally orange after fusing. The source of heat is removed, and the product of the reaction cooled. After dissolving it and passing air through the solution indigo is precipitated. The yield was not more than 9½ per cent. Care has to be taken to avoid too excessive heat and to prevent access of air.

The reaction is explained by the equations:—

On using anilido-acetic acid the same results were obtained.

To prevent the evolution of free hydrogen, which always means a reduction of the yield, the employment of a mixture of equal molecules of oxanilic acid and anilido-acetic acid was tried, but with no better result. The yield was really slightly lessened.

The idea to be realised by this experiment may be explained by the following equation:—

—A. L.

Synthesis of Indigo and Allied Dyestuffs. K. Heumann. Ber. 23, 3431—3435.

IN the synthesis of indigo from phenylglycocine, previously described by the author (this Journal, 1890, 1121), it seemed probable that isomers of pseudo-indoxyl were produced by the substitution in the benzene nucleus of hydrogen atoms in the meta- and para-positions to the nitrogen atom. To ensure the sole production of ortho-compounds, the author, in a further synthesis, sets out with anthranilic acid. By acting on this body with chloroacetic acid, phenylglycine-*o*-carboxylic acid—

was obtained. After recrystallisation from water, this compound appears as a yellow granular mass, melting with decomposition at about 200°; it dissolves with difficulty in cold water; exhibits a blue fluorescence in alcoholic solution. The ordinary methods of preparation of ketones were tried with a view to obtaining the CO group of this acid in the necessary position for the production of pseudo-indoxyl and indigo, that is, between the phenyl- and methyl-residues. A portion of the acid was, with this object, mixed with a slight excess of milk of lime, evaporated to dryness, and heated; the mass became coloured yellow or red, and the inner surface of the glass vessel, in which the experiment was made, became covered towards the top with a blue deposit of indigo. Towards the end of the reaction a brown oil distilled, which, when treated with lime, was found to generate indigo. When the same experiment was made in a retort from which the air was excluded by a current of hydrogen, no formation of indigo was observable; a turbid yellow-green aqueous distillate, on which a brown oil floated, was received. On exposure to air this distillate became coloured a pale green-blue; on addition of a few drops of caustic soda solution, blue flocks quickly separated, and the liquid became covered with a bronze-coloured pellicle. The yield of indigo was, however, unsatisfactory, most of the oil being resublimed. Assuming that the distillate contained indoxyl, barium hydrate was tried instead of calcium hydrate, with a view of retaining the same. The mixture of phenylglycine-*o*-carboxylic acid with a slight excess of baryta was evaporated to dryness and carefully heated, the mass, without any decomposition taking place, being coloured deep yellow. When the intensity of colour increased no more, the reaction was interrupted. On mixing the product with water, a blue precipitate of indigo was quickly formed on the surface of the liquid; the separation of indigo was hastened by a current of air. The precipitate was collected, freed from baryta by treatment with hydrochloric acid, and washed with water and afterwards with alcohol.

The use of baryta not being satisfactory for the reason that the mass was unequally heated through remaining unfused, alkalis were tried and found to give the best results. One part of phenylglycine-*o*-carboxylic acid was heated with 3 parts of potassium hydrate and 1 of water; towards 200° the mass commenced to colour yellow, changing afterwards to a rich orange. The heating was continued as long as the mass deepened in colour. After cooling, the product was dissolved in about 200 parts of water and oxidised by a current of air or by addition of acidulated ferric chloride, and the separated indigo was washed, first with water, next with dilute acid, and then with alcohol, and finally dried.

The author considers it probable that indoxylie acid—

is first formed in the above reaction, and that this body further decomposes into indoxyl and carbon dioxide.

The synthesis of indigo from phenylglycine-*o*-carboxylic acid is, with the use of potash, effected at a temperature 60° to 80° lower than that required with phenylglycine.

The process has been patented.—E. B.

On some Derivatives of Benzidine-*m*-Monosulphonic Acid.
A. Zehra. Ber. 23, 3459—3464.

THE author describes some derivatives of the benzidine-*m*-monosulphonic acid.

Sodium Salt of Diacetylbenzidine-*m*-monosulphonic Acid—

was obtained by heating the dry sodium salt with about the same quantity of acetic anhydride. It forms colourless needles, with difficulty soluble in cold water, easily soluble in hot water.

m-Dinitrodiacetylbenzidine-*m*-monosulphonic Acid—

was obtained by adding the theoretical quantity of nitric acid to a solution of one part of the sodium salt of the diacetyl compound in five parts of sulphuric acid. The temperature of the mixture ought to be kept below 5° C. The orange-coloured product is soluble in water and alcohol. On heating it with dilute sulphuric acid (1:2) on the water-bath—

m-Dinitrobenzidine-*m*-monosulphonic Acid—

was formed, with difficulty soluble in hot or cold water, easily in dilute mineral acids. By nitrous acid it is converted into a diazo compound, which forms a nearly insoluble blue-black with β -naphthol, a reddish violet with β -naphthol-disulphonic acid R, and a violet-black with β -naphthol-disulphonic acid G.

On reduction of the nitro compound with stannous chloride and hydrochloric acid—

m-Diamidobenzidine-*m*-monosulphonic Acid—

is obtained, forming a very stable hydrochloric acid salt. Ferric chloride produces a dark colouration, a black precipitate being formed at the same time; picric acid forms a perrate. By the action of the sodium salt of croconic acid an azine of the formula—

is formed, which gives an additional proof that the two amido groups are in ortho position to each other—A. L.

unsatisfactory. Still more unsatisfactory, however, is the extension of the above classification to colouring matters, for it is well known that the necessity for the employment or non-employment of a mordant depends more on the nature of the fibre to be dyed than on that of the colouring matter used, most dyestuffs being substantive towards some fibres and adjective towards others.

The nature of substantive dyeing is doubtless simpler than that of adjective dyeing, yet it is not understood. The exponents of the theory of dyeing have ranged themselves into two sets, one set advocating a mechanical theory, the other a chemical one. In addition to these, there is a small group who content themselves with comparing the action of textile fibres in absorbing colouring matters to the absorbent action of animal charcoal. As, however, nothing is known regarding the nature of this property possessed by charcoal, the analogy is of no service in increasing our knowledge of the nature of dyeing.

The adherents of the mechanical theory assume that the molecules of colouring matter leave the dye-bath and deposit themselves in between the molecules of the fibre, without entering into chemical union with the same. Against this view, it may be urged that nothing has as yet been adduced to support such an unusual hypothetical migration of molecules, it being impossible, in the whole field of natural science, to find any analogy to it. But the strongest objection consists in the fact that only certain dyestuffs possess the power of dyeing substantively, and these, again, behave differently with different fibres.

The chemical theory supposes that, in cases of substantive dyeing, a chemical combination between fibre and colouring matter takes place. This supposition is doubtless correct in certain rare instances. Thus, the researches of E. Knecht have shown that a combination in definite proportions takes place between the wool fibre and colouring matters of the class of nitrophenols. These colouring matters are, however, such as one would expect from observed indications, to chemically combine with the fibre mentioned; in the majority, and most important, of cases, no such definite combination can be shown to exist. This defect has been partially remedied by the above-named chemist, who has propounded a theory, to some extent supported by experimental proofs, to the effect that many of the cases of so-called substantive dyeing are, in the case of the wool fibre, really cases of adjective dyeing, the dyestuff combining with the launinic acid, which is slowly formed on boiling that fibre with water, and which, therefore, acts as a mordant, being itself contained in the wool fibre in a state of "solid solution." Although this hypothesis goes far to explain the character of certain cases of wool-dyeing, it affords no elucidation of the nature of the substantive dyeing of cotton and silk, both of which fibres are unaltered by prolonged boiling with water, silk, indeed, being dyed to some degree even from a cold bath.

A critical objection to the chemical theory is supplied by the behaviour of certain dyed colouring matters. Take, for example, silk dyed with Magenta. Such dyed silk has to be treated with moderately strong soap solution before it yields up any colour. It might be inferred from this that the Magenta-silk compound was of fair stability. To one's astonishment, however, on dipping the compound into absolute alcohol, the dye is almost instantaneously detached from the silk. This effect is the more striking as it is well known that no chemical affinity exists between alcohol and Magenta. Alcohol is a solvent for Magenta, nothing more. Let it be supposed, however, that these two bodies do combine and that the affinity of alcohol for Magenta is greater than that of silk for the same. The following simple experiment shows this supposition to be wrong:—On the addition of water to the alcoholic solution of magenta, the dye returns to the silk, the strength of the alcohol determining whether the dye remains in solution or attaches itself to the silk. Of such reactions as these, no explanation is given by the chemical theory of dyeing.

Relations between fibre, dyestuff and dye-bath, similar to those obtaining in the experiment just described, are found to exist in all cases of incomplete exhaustion of the dye-bath; a portion of the dye is absorbed by the

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

The Theory of Dyeing. O. S. Witt. Farber-Zeitung, 2, 1—6.

EXCLUDING the process of colouring textile fibres by the application of solid pigments by means of adhesive substances, such as glue or albumen, dyeing processes are classified as adjective when the intervention of a mordant is necessary, or substantive when no such assistance is required. This classification is wanting in precision, and is

fibre, the rest remains in solution. On removing the dyed material and introducing a fresh undyed portion, further absorption of dye is effected, but this may be repeated many times without the dye being completely withdrawn from the bath. The fibre, according to the chemical theory of dyeing, precipitates the dyestuff. Strange it is then that a large excess of the precipitant does not remove the last traces of dye, for there is no resemblance between this incomplete action and the ordinary case of incomplete precipitation so frequently observed in chemical reactions; in the latter the solubility of the precipitate causes the precipitation to be imperfect, but the above precipitate, that is, the assumed compound of fibre and dyestuff, is quite insoluble.

These and other considerations led the author to inquire whether there were not some other way of accounting for the phenomena of dyeing, which should be free from the objections mentioned, and induced him to look upon them as actions of solution. In order, however, to include the dyeing process as an act of solution, it becomes necessary to extend the theory of solution to the interaction of solids on solids.

To show that there is nothing irrational about such a view, the author quotes as examples precious stones and coloured glass, in which the colouring ingredients are in a state of solid solution in the mass of the same. That these solutions were once liquid is of no moment as regards the theory of dyeing. The process of substantive dyeing and, as is shown below, numerous cases of adjective dyeing, may then be considered as actions of solution. Facts in support of this theory may be plentifully adduced. According to the mechanical theory of dyeing there is in a substantively-dyed fibre a juxtaposition of fibre- and dye-molecules; the dyed fibre should, consequently, exhibit the colour of the dry dyestuff. But it does not. Fibres dyed, for example, with Magenta or Methyl violet, are red or violet and not bronzy-green. Fibres dyed aniline blue do not show the coppery-red hue characteristic of the dry dyestuff. On the other hand, there is an undoubted instance of mechanical dyeing in the case of indigo, and in dark shades of this colour the bronzy hue of dry indigo is readily seen. Again, shellac-varnish coloured with Magenta or Methyl violet is red or violet, but on evaporation, the alcohol, which is the common solvent of the resin and dye, is driven off, and the residue, although its constituents are in molecular juxtaposition, is bronzy, because the dyestuff is insoluble in the resin. A further proof is afforded by the consideration of the behaviour of a fluorescent dye, such as Rhodamine. Rhodamine in alcoholic solution shows a powerful fluorescence. If, however, it be evaporated in a thin layer on a glass plate, the residue is devoid of fluorescence. Similarly shellac-varnish tinted with Rhodamine fluoresces, and on evaporation, so long as traces of alcohol remain in the residual mixture, the fluorescence is visible, but on completely expelling the alcohol the fluorescence disappears. Now, silk which has been dyed with Rhodamine fluoresces. Evidently the dye is in a state of solution, precisely as it is when dissolved in alcohol or water.

The fact that all dyestuffs are not substantive is due to their different solubilities in the fibre-substances. This does not imply that adjective dyestuffs are insoluble in the fibres. As a matter of fact, all dyestuffs which are soluble in water are more or less soluble in the three typical fibre-principles, fibroin, keratin, and cellulose. If this were not so, a strand of cotton which had been dipped in a solution of Magenta, for example, should, on washing, readily part with the last traces of absorbed colour, as glass-wool does, when treated in the same manner.

This theory is not, however, concerned with the solubility or insolubility of dyestuffs in textile fabrics, but with the relative solubility of the same in textile fibres and in water. On the basis of this explanation, substantive dyes may be defined as such as are more soluble in the fibre principles than in water, and are, in consequence, extracted by the former from their solution in the latter. The operation of substantive dyeing is thus analogous to the extraction of substances from aqueous solution by means

of insoluble solvents. The extraction of Magenta from its aqueous solution by silk may be compared to that of resorcinol from the same liquid by means of ether. On agitating with ether an aqueous solution of resorcinol, the resorcinol leaves the water and passes into the finely-divided globules of ether, being more soluble in that liquid than in water. So it is with the magenta and silk, the dye is more soluble in silk than in water. The requisite fine state of division is here presented in the form of the silk fibre. Moreover, the fibre, being a colloid, is osmotic and permits the dye solution to penetrate through its molecular interstices. If, however, the solvent power of the dye-bath be increased by the addition of alcohol, or, what amounts to the same thing, that of the fibre decreased by the application of tannin matters, which, although possessing chemical affinity for the basic dye, nullify the solvent capacity of the silk, dyeing does not take place, the Magenta remaining in the dye-bath. With this conception of the nature of the process of dyeing, the object and necessity for the constant movement in the dye-bath of the material to be dyed are readily understood, as is also the necessity for the proper proportioning of the volume of dye-liquor to the amount of material to be dyed.

The effect of immersing cotton in a solution of Magenta may be compared to that of agitating an aqueous solution of resorcinol with benzene; resorcinol is soluble in benzene, but more soluble in water, and is therefore not extracted from water by benzene.

Again, the imperfect extraction of resorcinol from its aqueous solution by amyl alcohol is analogous to a case of incomplete exhaustion of a dye-bath.

From the above it would appear that the chemical nature of a textile fibre, in cases of substantive dyeing, is only of moment as affecting the solvent capacity of the same. Thus, fibroin dyes better than other fibres on account of its superior solvent power; keratin, again, has for most dyes a greater solvent power than cellulose; the solvent power of cellulose is, indeed, so little that there are only a few dyes which it is capable of extracting from water, and with some of these, for example, the stilbene dyes, it is found advantageous to decrease the solubility in water of the dye by an addition of common salt. It will now be understood how it is that the thick-walled linen fibre is so much more difficult to dye than thin-walled cotton, the latter presenting much greater surface than the former, and consequently being better adapted for extraction purposes.

Finally, the fact that Congo red, for example, dyes a scarlet colour on cotton, whilst its aqueous solution is yellow, and that numerous other dyestuffs dissolve in textile fibres with a colour different from that which they possess when in aqueous solution, finds numerous analogies in extraction processes; thus, the colourless isonitrolic acid dissolves in benzene with a blue colour; iodine, which is brown in aqueous solution, imparts a purple colour to chloroform, &c.

Turning now to cases of adjective dyeing, it will be seen that with them, too, dyeing is an action of solution. The solution, however, takes place, in the first instance, between the fibre and mordant. Once dissolved by the fibre, the function of the mordant is to precipitate and fix the dyestuff which comes into contact with it. An analogous instance of solution is easily found. As mentioned above, benzene is incapable of extracting resorcinol from its aqueous solution, but if benzoyl chloride or acetic anhydride be added to the benzene, the resorcinol is readily removed from the water, being at the same time converted into a corresponding ester. The benzoyl chloride and acetic anhydride here play the rôle of mordants.—E. B.

Import of Cotton Goods Containing Arsenical Dyes into Norway. Board of Trade J. January 1891, 33.

HER Majesty's Consul General at Christiania, in a report to the Foreign Office, dated the 20th December, with respect to the regulations affecting the importation into

Norway of cotton goods in the preparation of which arsenical dyes are used, says:—

"It appears from the report of the Christiania Sanitary Commission for 1889, that the textile goods of which the sale was prohibited in that year, on the ground of their containing arsenical matter in excess of maximum permitted under the Rules of the Commission, consisted, as in 1888, almost exclusively of British cotton prints.

"Out of 496 samples of textiles tested by the Commission last year, 55, or 11 per cent. (against 24 per cent. in 1888), were condemned in accordance with those rules.

"The principal colours were blue and white (22 samples), brown and white (eight), black and white (five), red and yellow (four), brown and yellow, blue and yellow, yellow and red (severally three samples), and the remainder (one sample of each) blue and black, blue and brown, blue, black and red, red, yellow and green, and red and white.

"I am informed that the test is more severe at Christiania than in most cities on the Continent.

"This will account for the growing preference given in this country to German, French, and Swedish cotton prints and dyed woollens.

"Indeed, it seems to be believed in Norway that the danger of using textiles coloured excessively with arsenical dyes is not fully recognised in Great Britain, whereas medical men in this country strongly insist on the existence of that danger, especially in the case of children and of persons in weak health.

"Arsenically-dyed bedclothes (blankets, &c.) are more particularly avoided under medical advice.

"Several British manufacturers of cotton prints, aware of this prejudice, now guarantee that their goods are 'free from arsenic'; but a more general care in selection of patterns suitable to this market should evidently be exercised."

PATENTS.

Improvements in Injection Tubes, Skewers, or Spindles employed in Machines for Dyeing or otherwise Treating Yarn in Cop or other Compact Form. A. Graemiger, E. A. Leigh, and S. Mason, jun., Manchester. Eng. Pat. 17,747, November 7, 1889. 6d.

THE object of this invention is the formation of a better joint between the open end of the hollow, perforated injection-spindles, employed in cop dyeing machines, and the cop-carrier or its nipple, thus ensuring a better result in the treatment of the cops, &c. This is effected by making the open ends of the spindles taper off slightly towards their extremities, the spindles then being fixed in the conical nipples, which, for this purpose, must taper inwards, instead of *vice versa* as hitherto; or the spindles constructed in this manner may be fixed directly in conical holes in the cop-carrier.—E. B.

Dyeing and Printing Animal and Vegetable Fibres with Dinaphthylidiquinhydrone, or with Beta-Naphthoquinone or Tetra-Oxydinaphthyl. B. Willeox, London. From The Farbenfabriken vormals, F. Bayer and Co., Elberfeld, Germany. Eng. Pat. 18,073, November 12, 1889. 4d.

DINAPHTHYLIDUQUINHYDRONE is effectually fixed on vegetable and animal fibres by the aid of metallic oxide mordants, shades being obtained with the chrome mordant similar to those obtained with anthragallol, and fast to light and soap. β -naphthoquinone, or the tetrahydroxydinaphthyl obtained by reducing dinaphthylidiquinhydrone, may be used instead of dinaphthylidiquinhydrone, being converted into the last-named compound during the course of the dyeing or printing operations.

Two claims are made: first, the employment for dyeing or printing purposes of the above-mentioned colouring matters; second, the use of the chrome mordant in fixing the same.—E. B.

Improvements in Machines for Dyeing, Bleaching, or otherwise Treating Fibres in a Raw, Spun, or Intermediate State of Manufacture. A. Graemiger, Manchester. Eng. Pat. 18,115, November 13, 1889. 8d.

THE material to be dyed, &c., is placed on a perforated disc or between two perforated discs or plates forming the piston of a pump, which works in a closed cylindrical liquor vessel containing inlet and outlet pipes, or in an open cylindrical vessel containing suitable arrangements for preventing the outflow of liquor on the downstroke of the piston. The dyeing, &c., is effected by the liquor being drawn or forced through the material on actuating the piston. For details of construction, arrangement of valves, &c., the original specification must be consulted.

—E. B.

Improvements in Apparatus employed in Dyeing Velvets, Plushes, and other Fabrics in the Piece, and in the Drying of Fabrics generally. B. J. B. Mills, London. From J. Valansot, sen., Lyons, France. Eng. Pat. 19,196, November 29, 1889. 8d.

THE subject of this invention is an apparatus for holding or carrying cloth whilst undergoing the operations of dyeing, washing, drying, &c. It enables the cloth when once wound on the framework of the apparatus to pass successively through all the operations mentioned without being detached from the apparatus. The apparatus is constructed of two discs placed at suitable distance apart on a central shaft. Each disc carries a number of radiating arms in which there are grooves for the reception of rods, which are fixed parallel to the central shaft and kept in their places by hooks or catches. The rods are formed of wood or of copper tubing with wooden cores, and, to prevent the cloth which is being treated from slipping, are wrapped with cloth or thread. Instead of rods, there may be used cords, belting, &c. attached to the arms in separate strips, or composed of one entire length, which is fixed to the centre and outer extremity respectively of the apparatus, and passed over hooks on the radiating arms and tightly stretched.

To fill the apparatus with cloth, it is necessary to place it horizontally on two supports, and after fastening one end of the piece to the innermost rod, to wind the cloth spirally over the succeeding rods, which are placed in position one by one as the winding progresses, the other end of the cloth being fastened to the outermost rod. The apparatus may be fixed so as to rotate either vertically or horizontally.

—E. B.

Improved Apparatus for Dyeing and otherwise Treating Textile Fabrics. C. Corron, St. Etienne, France. Eng. Pat. 19,863, December 10, 1889. 8d.

A dye-bath is fitted with three draw rollers working under the surface of the liquor, and with a pair of oscillating squeezing rollers mounted on levers above the bath. The squeezing rollers serve to lay the cloth in folds in a second bath contained inside the main dye-bath. One bath may be used for mordanting, washing, or brightening, whilst the other is used for dyeing, or "two colours or shades may be dyed at the same time." In connexion with this double bath, claims are made for a roller with right- and left-handed screw-threads for stretching in width the cloth under treatment; for a compressing roller for furling the fabric; an arrangement of steam pipes with "graduated perforations to aid in stretching the fabric in width;" and "the combination of the wheels and chains for driving the rollers and the cranks for working the oscillating lever."—E. B.

Improvements in Producing Azo-Colours on Cotton or other Vegetable Fibre. R. Holliday, Huddersfield. Eng. Pat. 20,061, December 13, 1889. 4d.

THE improvements relate to the process of producing azo colours on materials composed of vegetable fibres (Eng. Pats. 2757 of 1880; 1638 of 1881; and 2946 of 1882), and consist in combining in one operation the oiling of the fibre

and its impregnation with the phenol used. This is effected by mixing the oil—which, by preference, is such as is employed in alizarin-dyeing—with sufficient fixed alkali to develop the colour on subsequent treatment with the solution of diazo, diazo-azo, or tetrazo compound.—E. B.

Improved Mordant for Black Dyeing. W. Marriott, Huddersfield. Eng. Pat. 11,580, July 24, 1890. 4d.

A MIXTURE of "copperas, bluestone, and crystallised soda" is placed in an iron pan and gently heated until the carbonic acid of the soda has been expelled, when oxalic acid is added and the whole thoroughly mixed. The resultant mass, when dried and ground into powder, is employed along with logwood in the single-bath method to produce a fast black on woollen goods.—E. B.

Improvements in Apparatus for Dyeing Yarn. J. F. Peck, Providence, Rhode Island, U.S.A. Eng. Pat. 13,181, August 24, 1890. 8d.

A CYLINDRICAL cop-spindle holder is provided in its interior with a valve by means of which the passage of the dye-liquor through the cops is controlled, so that, while a large number of cops are immersed in the dye-liquor, only a few at a time are acted upon by the suction pump, a uniform shade of colour being in this way produced on all the cops. Claims are also made for improvements in a device employed for moving the spindle-carriers from one vat to another; in the employment of a moveable hose-pipe connected with the suction pump; and in several other mechanical arrangements which it is impossible to properly describe without reference to the drawings accompanying the original specification.—E. B.

Improvements in Dyeing, Bleaching, Washing, or otherwise Treating Cops of Yarn or the like, and Apparatus therefor. W. P. Thompson, Liverpool. From F. Kornfeld, Prague, Austria. Eng. Pat. 14,897, September 20, 1890. 6d.

HOLDERS of special construction are employed for receiving the cops, &c. to be dyed. Obstacle-plates or flanges project from the sides of the holders, and are inserted between the coils of thread after the cops have been placed in position. The purpose of the obstacle-plates is to produce a better penetration of the cops, &c. with the liquors "or gases" employed. The holders are cylindrical in the middle and terminate in conical caps with flanges projecting over the sides of the middle piece; they are placed in vertical rows over tubes connected with a liquor-vessel, their tops projecting into a similar liquor-vessel placed above, and the dye-liquor, &c. is pumped through the cops from one vessel to the other.—E. B.

VII.—ACIDS, ALKALIS, AND SALTS.

On Guttman's Improvements in the Manufacture of Nitric Acid. H. Andersch. Zeits. f. angew. Chem. 1890, 619.

GUTTMANN states (Zeits. f. angew. Chem. 1890, 507; this Journal, 1890, 862) that with his battery the distillation of nitric acid can be conducted as hot as may be desired, and that a great evil of the retorts is that through foaming the contents may easily be carried over into the delivery pipes. The author considers it a very doubtful advantage to be able to work as hot as may be desired, as the nitric acid is easily decomposed by a too elevated temperature; and, further, that when the charge is properly adjusted to

the size of the retorts, the contents are never carried over into the discharge pipes. Guttman's system of cooling in pipes will no doubt operate more quickly, but a weak point is the number of joints which have to be made. Under the old system, for the complete condensation of the acid from a charge of 3–3.5 hectokilos, of saltpetre in one retort, four

THE MANUFACTURE OF NITRIC ACID.

bottles of the size shewn in the figure are necessary in winter, and five in summer.—W. M.

The Alkali Manufacture in Russia.

THE Russian Chemical Society has just recently received a communication, with a sample of the first output of Russian bleaching powder, from P. K. Ushkoff, of Elabonga, in the province of Viatka, who has just started manufacturing bleaching powder on a large scale from native products. This is considered a very important step in the growth of Russian chemical industry, as the whole of the bleaching powder hitherto required for home industries had been imported from abroad (about 10,000 tons per annum).

The same manufacturer has nearly completed his arrangements for manufacturing soda ash and caustic soda by the Leblanc process.—N. W. T.

PATENT.

The Production of Sulphate of Ammonia ($\text{SO}_4\text{NH}_4\text{O}$) from the Nitrogen of Marshy Moors or Meadow Land Moors, and Apparatus therefor. W. L. Wise, London. From H. Grouven, Leipzig, Germany. Eng. Pat. 1136, March 21, 1878. (Second Edition.) 1s. 3d.

ACCORDING to the patentee, "marshy or meadow land moors contain up to 3.8 per cent. of nitrogen." The method of obtaining this nitrogen (or 98 per cent. of it) is based on the results of investigation, "that the intrinsic nitrogen value of the moor is for the greater part contained in its proteins of plants, and does not, as has hitherto generally been assumed, exist in ammonia salts." The process is divided into the following main operations:—

"(1.) Preparation of the excavated moor or bog for further treatment." "(2.) The conversion of the moor or bog to ashes, steam, gas, and vapours, the air being excluded, and under the influence of certain degrees of heat." "(3.) The decomposition of steam in the presence of the gases and vapours by means of the adoption of a peculiar contact mass and at certain degrees of heat for the formation of carbonate of ammonia in gaseous form." "(4.) The condensation of a part of the carbonate of ammonia gas formed." "(5.) The conversion of the non-condensed carbonate of ammonia gas to sulphates of ammonia by the use of a peculiar chalk gypsum (sulphate of lime) in form of marbles or very small balls at certain degrees of heat." "(6.) The conversion of the condensed carbonate of ammonia to sulphate of ammonia." "(7.) The filtration and the evaporation of the solution of sulphate of ammonia and the production of the dry sulphate of ammonia." For details of the apparatus, &c., the specification must be consulted.

Improvements in Furnaces for Concentrating Sulphuric Acid. C. Négrier, Paris, France. Eng. Pat. 14,022, September 6, 1890 (Internat. Conv. April 26, 1890). 6d.

THE acid runs from the reservoir *a* by means of the syphons *a'* upon the slab *b*, and thence by the tubes *b'* into the concentrating dishes *C*. The dishes are placed in pairs,

THE CONCENTRATION OF SULPHURIC ACID.

each successive pair lying below its predecessor. They are made of porcelain, whilst the shelves *D* are of iron and are pierced with holes to allow of the more ready escape of the acid in case of fracture of the dishes. Each dish rests upon asbestos tissue and is surrounded with sand to the level of the upper rim. The fire is situated at *E*, whence, as the acid becomes more and more concentrated in its passage downwards, it meets with gases of increasing temperature. It issues finally very highly concentrated at *Z*. The vapours evolved from the dishes are aspirated off through a leaden tuyere *V*. The furnace gases leave at *X*, and their heat may be utilised in a similar apparatus for a preliminary concentration of the acid.—S. G. R.

PATENTS.

Improved Means of Manufacturing Hollow Glass-ware and Glass Tubes by Machinery. D. Rylands, Barnsley. Eng. Pat. 17,168, November 4, 1889. 11d.

THE inventor describes mechanical arrangements for ensuring the molten glass being level or nearly level with the plunger after it has come sufficiently in contact with the top molten metal to form the mouth or top of the hollow glass-ware; also for securing a smooth rim and top; for passing the outer mould along fixed bars, in combination with a stationary and blowing plunger and an inner pressing mould; and for the manufacture of glass tubes.—E. G. C.

Improved Means or Apparatus for withdrawing Molten Glass or Molten Metals from Furnaces and Controlling the Outflow thereof, also applicable for Conveying Liquids or Chemicals of a Liquid Nature from Larger to Smaller Vessels or Receptacles. D. Rylands and J. W. Horner, Barnsley. Eng. Pat. 17,932, November 11, 1889. 8d.

See under I., page 36.

Improvements in the Manufacture of Glass Tubes, Sheet Glass, and other Glass Ware. D. Rylands, Barnsley. Eng. Pat. 19,734, December 9, 1889. 8d.

AN oscillating or swinging motion is imparted to the tube mould, which is of a special construction, described in detail in the specification.—E. G. C.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Methods of Preserving Timber at the Vienna Exhibition. R. Rittmeyer. Dingl. Polyt. J. 278, 221—234.

ONE of the latest methods of impregnating timber with a preservative agent is that devised by Pfister. The apparatus necessary is portable, and is intended to be taken to the spot where the trees to be treated are felled, so that impregnation can be carried out there. The entire trunk is not saturated, but only an inner cylinder of wood as large as may be available. A plate of suitable size provided with a cutting edge is forced into the squared end of the stem and held in position by chains attached to hooks driven into the trunk and tightened by a screw. It is kept central while being fixed by a stake passing through the aperture which afterwards serves for the attachment of the pipe conveying the preservative fluid. Two men can thus prepare a tree in three or four minutes. Any cracks, longitudinal or transverse, are stopped up before the plate is put on to prevent unequal diffusing of the preservative liquid or its too easy exudation. A precaution that should be observed consists in felling no more trees than can be treated the same day, as impregnation is effected through a freshly-cut surface more readily than through one that has been long exposed. The liquid used is a solution of zinc chloride of a specific gravity of 1.008 for timber that is to be used under cover and 1.010 for that which will be exposed to the weather. Stronger solutions raise the cost of preservation without corresponding advantage, the expulsion of the substances instrumental in setting up putrefactive change being as complete with a weak as with a strong solution. In a process of this nature in which a portable apparatus is used, some consideration must be had to the relative advantages of taking it to the timber and the reverse plan, as the water necessary to dilute the strong solution of zinc chloride sent with it may be not available or unsuitable if found near the trees to be treated. A water containing calcium carbonate must be neutralised with hydrochloric acid before being used, as it would otherwise precipitate a portion of the zinc. The solution having been prepared and the plate fixed, the pump is set in action and the preservative fluid forced in, displacing the sap naturally present in the tree. As the latter exudes from the free end of the stem it has a specific gravity varying with the kind of wood, its age and situation, sometimes reaching 1.0045. As the process continues practically pure water passes out for a while, and then the specific gravity of the expelled liquid rises again until it reaches that of the fresh preservative, showing saturation to be complete. By starting with a liquor about 50 per cent. stronger than that mentioned above as of the usual concentration, and diluting it to the proper extent by the weaker liquid first expressed from the tree after the expulsion of the sap, considerable economy, more particularly in the quantity of water used, which is sometimes a very desirable consummation, results.

On the average 360 litres of solution are necessary for 1 cub. m. of beech.

Pfister states the cost as ranging from 4d. to 6½d. per cubic metre, according to the extent to which the partially exhausted liquor is utilised, the specific gravity being in all cases 1.010.

The timber should be allowed to remain some time after impregnation before being worked in order to permit the full formation of insoluble compounds with the preservative.

Zinc chloride is used in preference to other salts on account of its cheapness, but for special purposes various liquids may be employed. Thus the wood may be coloured red throughout by dilute sulphuric acid, the depth of colour increasing with the concentration. Mahogany red is obtained by using dilute nitric acid, while weak iodine solution gives a brown shade. Greyish black and black are produced by injecting ferric chloride followed by tannin. The wood may be rendered non-inflammable by impregnating it with an aqueous solution of alum, to which a concentrated solution of zinc chloride in the proportion of 10—25 litres per hectolitre has been added. In estimating the economy of carrying on the process in the forest itself it must not be forgotten that either the impregnated timber must be worked up on the spot, or a greater freight be encountered; for example, the increase in weight, due to impregnation, of a freshly-cut sleeper 2.5 m. × 25 cm. × 15 cm. amounts to as much as 12—30 kilos.

The chief disadvantage of the process lies in the fact that the impregnation is somewhat irregular, as the following table of analyses of the two ends of sundry sleepers demonstrates.

PERCENTAGE OF ZINC CHLORIDE.

Thick End of Log.	Thin End of Log.
1.12	0.27
1.21	0.39
1.09	0.80

The older Boucherie process, in which the timber is impregnated by a moderate pressure due to a head of liquid in the containing vessel (about 10 m.), though slow, gives a considerably more even distribution of the preservative.

The sleepers used on the Hungarian State railway are treated with zinc chloride solution forced in by steam pressure (Dingl. Polyt. J. 271, 230). Using a solution of sp. gr. 1.015 at 17°C., a fairly complete impregnation is obtained though the distribution is still somewhat irregular; thus a sleeper containing 1.222 per cent. of zinc chloride at the end had only 0.364 in the middle. Extensive experiments have been made to test the efficacy of the process. In those cases where rapid decay was observed it was satisfactorily traced to imperfect saturation, which may be due to the wood being already attacked by fungoid growths, such wood being difficult to impregnate, or to imperfection in the execution of the process. A travelling plant of this description has been devised for railway work.—B. B.

On the Use of Decomposed Granite Sand as a Natural Cement in Japan. J. Takayama. Dingl. Polyt. J. 278, 275—286.

In some provinces of Japan a sand consisting of decomposed granite is found and is used as a cement in admixture with slaked lime. The author gives analyses of samples of the sand from different localities which show that it contains a finely divided clayey material which, in combination with slaked lime, has the property of hardening. Numerous experiments are detailed to show which is the best proportion in which to mix the sand and lime and showing the influence of fresh water, sea water, and the action of frost upon the cement so formed. The cement is not so strong as Portland cement, but may be substituted for it in many cases on account of its cheapness. Fresh water has no action on it, but it is soon destroyed by the action of salt water.

The Basic Process as applied to Copper Smelting.

P. C. Gilchrist.

See pages 4—13.

On the Darby Process of Recarburising Iron. A Paper read at the International Congress of Iron and Steel Manufacturers at Pittsburg, U.S.A., October 1890.

In experiments for the production of steel the chief point in the solution of the problem is always the introduction into or the removal from the iron of a determinate quantity of carbon. In producing steel containing a desired percentage of carbon by the Bessemer process, two methods present themselves. By the one, the process is stopped when the bath possesses the desired contents of carbon; by the other the bath is completely decarburised, and then the wished-for carbon added in the form of ferro-manganese, spiegeleisen, &c. In Germany the latter method only came into use and was retained when the Thomas-Gilchrist process for the production of steel low in phosphorus from highly phosphoric iron in the basic converter came successfully into use, the more so, as from the nature of the process, before dephosphorisation takes place, complete decarburisation is necessary. But, while by the old acid process the carburisation was readily effected by the simple addition of spiegeleisen, &c., the Thomas-Gilchrist process brought with it new difficulties owing to the interference of the oxides always present in the basic process, and the phosphoric acid of the slag. Although methods of manipulation were resorted to with success for overcoming these difficulties, still the production of low phosphorus steel high in carbon could not be accomplished so readily as not to make the introduction of another simple method of carburising desirable. The circumstances are similar as regards the basic and acid open-hearth processes. Many methods of introducing carbon were tried in many quarters and all of them were based on the known fact of the great affinity between carbon and iron at high heats. It was sought to reduce and carburise the bath of steel by the introduction of carburetted gases, by the addition of tar, petroleum, &c., as well as many mixtures of these substances with solid bodies such as burnt dolomite. None of these attempts led to a practical working result until Darby, the managing director of the Brymbo Steel Works, succeeded in solving the problem. Having remarked an increase of carbon which took place in welding two pieces of steel in a coal fire, he brought fluid steel into intimate contact with solid carbon, the result being a rapid absorption of the carbon by the steel. On this experiment he founded his patent process by which fluid steel can be carburised by filtration through pieces of carbon in the form of graphite or wood charcoal, &c. (this Journal, 1889, 546 and 549; 1890, 1134). He employed for this purpose a cylinder of sheet iron lined with refractory material and open at the top and closed at the bottom by a plate pierced by numerous holes. This cylinder was filled with the carbonaceous material and inserted either between two steel ladles, or between the Siemens furnace and a steel ladle, and the fluid steel was allowed to flow through it. It was soon found that the absorption of the carbon was so rapid that the long time required for filtration by this method was unnecessary. Darby therefore substituted for the cylinder a pot lined with refractory material, with a bottom perforated by numerous holes. The carbon was not placed in this, but above it was placed a receptacle containing the roughly broken carbonaceous material. This receptacle had a side valve by the opening of which the carbon was allowed to fall faster or slower into the pot where it mixed with the steel which became carburised and flowed out through the perforated bottom.

The loss of carbon (graphite) by this method by burning is from 15—20 per cent.; with coke the loss is greater. Darby's experiments extended only to the carburising of open-hearth steel, and he succeeded in making excellent steel from phosphoric raw material containing any wished-for percentage of carbon to upwards of 0.9 per cent.,

containing only traces of other bodies and distinguished by its toughness. It has been worked up into chisels, knives, wires, &c. with the best results. The steel rolled very well, although only small additions of ferro-manganese or ferro-silicon were made.

In order to extend the system to the Bessemer process, Darby entered into an arrangement with the Phoenix Company of Laar, near Ruhrort-on-the-Rhine. When tried with the basic Bessemer process, although the steel was readily carburised it would not roll, the ingots falling to pieces in the rolls. This was found to be due to the oxidation caused by the screaming of the metal during four minutes through the 60 small holes of the perforated bottom of the carburising pot, and it was sought to prevent the oxidation by substituting one hole of suitable diameter for the 60 small holes. An improvement resulted, but the steel did not yet roll sufficiently well. Finally, the observation that the finely-ground coke is immediately absorbed on first contact with the metal, led to the adoption of the plan of allowing the carbonaceous material to be added direct to the stream of molten metal flowing from the converter before it reached the casting ladle, whilst the slag was retained in the converter until the carburisation was complete, by means of a suitable plate or block of refractory material held at the mouth of the converter whilst the metal was being poured. A table showing some of the results obtained is given in the original paper. During the month of June, at the Phoenix Works, 70 per cent. of the steel-rail charges and also a number of charges for hard and welding Thomas steel were produced in this way. The same addition of ferro-manganese is required as in the Thomas process, but no spiegel is needed. The advantages are enumerated as follows:—1. In the basic Bessemer (Thomas) process:—the carburising takes place in the almost complete absence of the slag, rich in oxides and phosphoric acid, consequently it proceeds with certainty, is accompanied by no important rephosphorisation, and is practicable for any desired percentage without simultaneously increasing the manganese. By the omission of spiegel, a considerable economy is effected. 2. In the Bessemer (acid) process:—the carburisation takes place up to the highest grade of hardness with far greater safety than by the help of spiegel and without the increase of manganese consequent upon the use of spiegel. Here also a considerable economy is effected due to the saving in spiegel. 3. In the open-hearth process:—for the acid and basic open-hearth processes the advantages are nearly identical with those for the Bessemer and Thomas processes; the very considerable cost of the ferro-manganese and ferro-silicon being wholly or for the most part avoided. In combination with the basic open-hearth process a steel can be made for many industrial purposes that can compete successfully with crucible steel.

By the addition of, at the outside, 0.04 per cent. of aluminium to the bath a steel has been produced absolutely free from porosities and eminently fit to be used for railway tyres.—H. S. P.

Quicksilver Mines and Reduction Works. Eng. and Mining J. 1890, 50, 265–266.

This paper is a statistical abstract of the eleventh census of the United States Geological Survey on the production of quicksilver. Only two States produce any quantity of this material—California and Oregon. The former yielded in 1889, 26,164 flasks, each containing 76½ lb., and the latter produced only about 20 flasks, the total yield in 1888 being 33,250 flasks. At present there are only 11 mines with 36 furnaces in work, while there are 6 mines with 7 furnaces closed on account of litigation, low prices or want of funds, but which anticipate resuming when the price of quicksilver rises. The yield in California was obtained from 93,000 tons of ore, at a cost of 881,401 dollars, of which 73 per cent. was paid for wages, 25 per cent. for supplies, and 4 per cent. for other expenses. The cost per flask for production ranged from 65 to 21 dollars with an average of 33 dollars, while the market price fluctuated from 50 to 40 with an average of 45 dollars. The highest percentage of

quicksilver in the ore was returned for a lot of 200 tons at 2.295, the lowest at 0.286, and the average yield for all the ore roasted was 1.088 per cent.

It appears from the statistics that during the last 10 years the United States production has gradually fallen from about 60,000 to 26,000 flasks, and while the Almaden mine has kept up a steady yield the Italian mines have increased from 3,400 to 10,000 flasks, and the Austrian mines from about 10,000 to over 15,000 flasks. The grand total production for 1889 of 101,236 flasks is about 8,000 below the average for the 10 years. The paper contains a table of the yield, price and approximate value of the quicksilver from Californian mines for each year from 1850 to 1889, and also a statement of the estimated value of each and all the mines and works there at the present time.—A. W.

See under XXIII., page 67.

A New Method for Precipitating and Collecting the Gold in Chlorination. L. D. Godshall. Eng. and Mining J. 1890, 50, 620.

SOME time ago, C. H. Aaron in one of his writings mentioned a new precipitant for gold, with which the writer has experimented for over a year. It is precipitated sulphide of copper. This is, undoubtedly, far superior to anything hitherto in use, but it requires certain precautions.

In view of the difficulties always met with in the perfect separation of the gold and copper, the writer made further experiments in order to ascertain if other metallic sulphides might not answer the purpose of the copper sulphide, and found both on the experimental and the commercial scale that precipitated iron sulphide acted similarly to the copper sulphide in every way, and presented far less difficulty in the subsequent separation of the gold and iron; the use of the latter is therefore recommended by the writer as being preferable in every way to copper sulphide. Not content with this discovery, a number of experiments were made with precipitated lead sulphide, and this was found to be equally effective with the two sulphides already mentioned. Reduction of the gold is in this case extremely simple. The only possible objection that can be made to iron sulphide as compared to copper sulphide is that the former oxidises a little more readily than the latter, also that, in barrel chlorination, there is always present in the gold solution more or less free acid; small as the quantity generally is, when the liquid is heated, the acid has a slight solvent action on the iron sulphide, while it does not affect the copper sulphide. These properties make it necessary to replace the iron sulphide a little more frequently than the copper sulphide, but this disadvantage is very slight when compared with the difference in cost and trouble in the reduction of the copper sulphide. The reactions produced by these three sulphides are similar to that produced by H_2S . They are—

It will be seen by the above reactions that, as the gold is precipitated, the precipitant is being gradually, according to the amount of gold present, converted into a soluble chloride and dissolved, consequently it must be renewed from time to time.

The precipitate containing the gold should not be taken out too frequently, as this will simply cause needless work in the reduction and separation. Whenever the sulphide seems nearly exhausted the filter need not be cleaned out, but simply more freshly precipitated sulphide added to it. The strong canvas used for protecting the fine filtering muslin or linen should be replaced at times by a new piece, as the action of the free acid may and will in time render the fibres rotten and weak, and liable to tear, thereby causing a loss of the gold.

PATENT.

Improvements in the Tempering, Annealing, or Treating of Castings or Forgings of Copper, Nickel, Cobalt, and Aluminium, and of Alloys of these Metals with each other or with Manganese, Cast or Wrought Iron or Steel. A. Eyraud, Paris, France. Eng. Pat. 17,890, November 9, 1889. 4d.

A BATH of molten lead, zinc, or other fusible metal or alloy is used for tempering metals instead of water, saline solutions, fatty substances, &c., the advantages being that the bath has a high conductivity, does not evolve gaseous substances, and can be easily maintained at a given mean temperature. The use of this bath for large forgings and for armour plates in which the percentage of carbon exceeds 0.45 per cent. has already been patented by the author (Eng. Pat. 10,823 of 1886). The present patent refers to its application to copper, nickel, cobalt, aluminium, &c., and to alloys of these metals with manganese, cast and wrought iron and steel. The resistance of these alloys to shock and to penetration by projectiles is considerably increased by immersion when hot in metallic baths.—H. K. T.

ERRATUM.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

The Heroult Process of Smelting Aluminium Alloys. F. P. Dowe. Washington Meeting of the American Institute of Mining Engineers. Ironmonger, 1890, 377—378.

THE Heroult process consists in electrolysing a mass of molten alumina (Al_2O_3), and at the same time alloying the separated aluminium with a heavy metal, the heat necessary for the fusion of both the alumina and the alloying metal being supplied by the direct passage through the molten mass of an electric current of high amperage and low voltage. The process has been in active operation at Neuhausen, in Switzerland, for about two years. It is also in active operation in Froges, in Southern France. Both these locations were selected for this purpose on account of the presence of large and desirable water powers. The apparatus consists of a carbon containing vessel, which may be a single crucible for small operations, or may be built up of slabs or blocks of carbon for large and industrial operations. When built up of slabs or blocks, the whole is surrounded by an iron casing. In the earlier crucibles this iron casing was cast around the carbon, in order to secure close electrical contact. This, however, has been found unnecessary; and for the later crucibles the casings consist of plates bolted together, while pulverised carbon is packed between the carbon blocks and the iron. Electrical conductors are united direct to this iron casing, and the current passes from this through the carbon lining to the interior of the crucible. By this arrangement the crucible forms a part of the electric circuit, and in the earlier stages of the process is the cathode. When, however, the metal within the crucible melts, the melted metal serves as the cathode during the running of the process. A single carbon rod may serve for the positive electrode or anode in small operations. For large and industrial operations it was formerly necessary to build up compound anodes of slabs of carbon, as then it was impossible to get large single slabs. These small slabs were held together by dowels, either of carbon or of the heavy metal of the alloy, and clamped together at the top. By recent work at Froges, it has, however, been possible to manufacture single pieces of carbon of any desired size to serve as anodes. From

these very much better results are obtained than from the built-up anodes. One of the great difficulties with the latter is that, even with the utmost care in their preparation, and testing the plates before use, they will crack during the operation, and the pieces, falling down, are apt to cause short circuits. Moreover, when a plate cracks it becomes necessary to interrupt the operation and remove the broken piece. On account of the high heat in the furnace this is a disagreeable operation. With all the large anodes, whether built up or solid, metallic side-plates are used. These are clamped tightly upon the anode and extend a short distance into the furnace when new. They serve to protect the heated portion of the anode outside the furnace from oxidation, and they conduct a portion of the current, and thereby lessen the outside heating. As the process goes on and the anode is consumed and lowered into the furnace, these plates gradually melt, and furnish heavy metal to the alloy. As the plates melt away the clamps are raised from time to time. The anode is suspended from a crane provided with means for its ready adjustment within the crucible. In starting the process in a cold crucible, a suitable amount, say, of copper, is placed upon the bottom of the crucible, and the current is then allowed to pass. This soon fuses the copper, which forms a bath of molten metal, and thereupon becomes the cathode. Alumina is now added, and the anode is slightly raised. In the intense heat thus produced the alumina melts and forms a layer above the melted copper and becomes an electrolyte. The current passes through it and it is decomposed, the aluminium separates at the cathode of molten copper, and alloys with it, while the oxygen goes to the anode and combines with the carbon. It will thus be seen that the process is electrolytic in its operation. In the ordinary operation of the process the distance between the electrodes is maintained at about 3 mm. At a suitable point in the circuit is placed a large ampère-meter, by watching which the workman can judge as to the distance between the electrodes, and raise or lower the anode as required. Alumina and copper are added from time to time as the operation of the process requires, and the reduction is continued until the crucible is full of metal, when it is tapped into a casting-ladle, and the current stopped. A considerable portion of melted alumina always flows out of the crucible after the alloy, and this is returned to the crucible during the next run. As soon as the crucible is empty the tap-hole is stopped and the proper amount of copper added, which is melted by the residual heat of the crucible. The current is again turned on, alumina added, and the operation of reduction resumed. From 10 to 15 minutes are required for this work.

As soon as the metal in the ladle has cooled sufficiently it is cast in iron moulds. This cycle of operations is repeated so as to constitute a continuous process. Nothing but copper and alumina are charged into the furnace. As the copper and aluminium are withdrawn in the form of an alloy and the oxygen passes off as gas, there is no slag or refuse of any kind arising from the operation. As the anode is consumed in the process it is gradually lowered, and when reduced to a stump replaced by a new one. This is usually done at tapping-time, and takes from 20 to 30 minutes. With the built-up anodes formerly used, it was necessary to heat up the anodes gradually, and generally an hour was consumed; but with the new block-anodes the current can be turned on at once. The reading of the ampère-meter is an excellent guide at all times as to what is going on within the crucible. When everything is moving along smoothly and properly there is simply a slight oscillation of the needle. Sudden or wide variations indicate some irregularity in the operation. In irregular work the position of the anode with reference to the cathode and the melted alumina is clearly shown. If the current pass between the melted alumina and the anode by an arc, if the anode dip into the alumina, but not far enough, or if too far, each condition will be shown by the position of the needle upon the circle; while if by any means the anode comes within are-distance of the melted metal at the bottom of the crucible, the fact will be unmistakably indicated upon the ampère-meter by a sudden increase in the number of amperes generated. This last

condition is also clearly shown by a number of other circumstances. When copper alloys are made there will be a copious volatilisation of the metal, and the flame at the charging-opening will be strongly tinged by it.

The proportion to be observed between the alumina and copper added varies under different circumstances. It is designed to produce at one operation an alloy containing a high percentage of aluminium. Alloys as high as 73 per cent. of aluminium have been produced; but under certain circumstances it is more economical to run from 35 to 40 per cent., and again at times it is more desirable to produce a 25 per cent. alloy. All things being considered, the 25 per cent. alloy is probably the most economical to produce, and may be taken as the standard. With proper care, and barring accidents, the grade of metal produced can be held with much uniformity. The maximum variations need not exceed 1 per cent. of aluminium. The percentage of aluminium that can be introduced into the alloy by this process is governed by the question of specific gravity. Since the specific gravity of alumina is 3.7 to 4.1, and the specific gravity of aluminium only 2.6, the limit in the percentage of aluminium is reached when the product becomes light enough to float upon the melted alumina. Practical work has shown that when the copper alloy reaches about 65 per cent. of aluminium, it begins to rise and cause trouble by short-circuiting between the sides of the crucible and the anode. When 73 per cent. aluminium is reached, there is so much short-circuiting from this cause that the process must stop. The loss of material varies with the percentage of aluminium introduced into the alloys. In making a 20 per cent. bronze, the loss of copper is from 5 to 6 per cent., but in making a 30 per cent. bronze, it may rise to 10 per cent. Owing to the high temperature and the rapid evolution of gas at the anode, there is considerable loss in alumina carried off mechanically by the gases, which may amount to 30 per cent., but with suitable means for recovering the solid material in the fume this has been greatly reduced at the Froges Works. When the process is in smooth working condition, the flame and smoke are alike light coloured. When, however, a short-circuit occurs, the flame becomes tinged with copper and is very much darkened.

Other metals besides copper can be used to alloy with the reduced aluminium, the only limitation being that they shall not be volatile at the temperature of the operation. The rich alloys produced in the furnace are very hard and brittle. They are not fit for any direct application. To prepare the useful alloys, these rich products are diluted to the proper degree by the appropriate metal for each case. While this process is more particularly designed for the reduction of aluminium, yet it is also adapted to the reduction of other refractory metals. Silicon copper has been thus prepared upon an extensive scale. Since the current required is different from that used for any other purpose, in that it must be of large quantity and of low intensity, the dynamo has to be specially built for this purpose. Machines for such abnormal current have never before been called for, and when the output is compared with the low speed at which they run, they may well be classed with the largest dynamos which have ever been built.

The construction of these gigantic machines was undertaken by the Oerlikon Machine Works, Zurich, Switzerland, and C. E. L. Brown's construction of the armature, in which the winding is passed through holes in the core, is particularly adapted to this application. The field of the dynamo is of the multipolar type, having six poles. It is made in one casting, in order to avoid all joints, and weighs 10,000 kilos. The exciting of the field-magnets is effected by a separate machine. The armature is of the usual Brown type, with embedded wires, but contains two distinct circuits, each having its own commutator. The winding consists on the outside of round copper bars, and on the inside of flat copper plates, placed in grooves planed out of the wood lining, so that the plates are firmly held, and at the same time insulated. There are six sets of brushes, making in all 72. Although cross-connections between the equi-potential coils are not absolutely necessary, yet they have been provided. Copper bars conduct

the electric current from the machines to the furnace. The two machines originally built for the works at Neuhausen were connected direct to a Jonval turbine. They were designed to give a current of 6,000 amperes at 20 volts, when running at 180 revolutions. It was found in practice, however, that they could be worked up to 30 volts. The present plant at Neuhausen consists of two 600 horse-power machines running on vertical shafts, and one 300 horse-power machine.

The process has been in operation at Boonton, New Jersey, for a short time. The installation here consists of a Victor 32½-inch turbine-wheel, supplied with water through a 6½-foot flume, with a fall of 28 feet. This, at 220 revolutions, is designed to give 220 horse-power. Coupled direct with the turbine is a Brown dynamo of 150 E.H.P., which furnishes a current of 3,500 amperes at 33 volts. A small 15-horse power exciting dynamo is used with the large machine. There are two furnaces, one 43 in. square on the outside, built up of carbon plates, giving a crucible of 9 in. by 16 in. and 19 in. deep, and a smaller one for experiments. This crucible has a capacity of 200 lb. of contained aluminium in 24 hours, after making due allowance for stoppages at casting, changing anodes, and for minor repairs to the crucible. The anode first used consisted of 10 plates, 6 × 12 × 40 in., bound together at the top by a specially designed clamp, to which the electric conductors are attached. Upon the outside of the anode were placed plates of copper clamped at the lower ends firmly against the carbon plates. At present the solid block anodes are used exclusively. In preparing the crucibles for work a layer of alumina is spread over the top, and upon this slabs of carbon are placed to form the cover, leaving just sufficient opening in the centre to permit the easy movement of the anode. Upon the front an opening is left through which the materials are charged. The grout of alumina serves to insulate the cover from the body of the crucible. The current is brought to the crucible through four large copper bars, no particular care being taken to insulate them, since a small loss in amperes will not much affect the working of the process. For raw materials the purest artificial alumina and Lake copper are used in the regular running of the furnace. Of these, about 25 lb. of alumina and 30 lb. of copper are charged at intervals every hour. Two or three castings are made during the 24 hours. Early in March a test-run was made to determine the general efficiency of the plant. This run lasted 12½ days. During that time 10,000 lb. of bronze, averaging 22.1 per cent. aluminium were produced. The total loss on the copper was only 6.4 per cent. Each casting of this run has been analysed, showing a metal of remarkable purity. The following are representative analyses by F. M. Simonds:—

RICH ALUMINIUM BRONZE.

Run.	Al.	Cu.	Si.	Fe.
23	28.41	71.16	0.11	0.33
30	26.35	73.25	0.11	0.29
36	24.83	74.80	0.11	0.26
37	26.66	72.95	0.12	0.26
49	19.65	80.15	0.14	0.07
51	21.95	77.60	0.12	0.33

A considerable portion of the impurity consists of iron introduced from the tools used at tapping. The tap-hole is usually very hard, but by an improved method of tapping it is hoped to reduce the percentage of iron in the product. One of the chief objects in setting up this small plant was to determine the applicability of a number of American raw materials for this process; and a considerable portion of the time is occupied in this work of testing. The following series of tests, made by Tetmeyer, of Zurich, on metals produced at the Swiss works, shows the general character

of the merchantable alloys prepared from the product of this process :—

PATENTS.

Improvements in the Manufacture of Plates for Use in Secondary Batteries or Electrical Accumulators. A. Reekenzaun, London. Eng. Pat. 18,755, November 22, 1889. 6d.

THE inventor causes streams of sparks or an arc to play between the lead plate to be treated and another conductor, in the presence of air, oxygen, and other gases. The surface becomes oxidised or otherwise acted upon so that the active material of the accumulator is readily produced thereon. In a particular case 2 ampères at 40 volts are said to have given good results. *Continuous* sheets, ribbons, or wire are treated by preference, which are then cut up to the required shapes.—E. T.

Improvements in Elements for Voltaic Batteries. D. G. Fitzgerald and A. H. Hough, London. Eng. Pat. 20,856, December 28, 1889. 6d.

THE improvements relate to methods of applying the "lithanode" (Eng. Pats. 4671 of 1885 and 16,608 of 1886, also this Journal, 1887, 146 and 558) material to the metallic supports. To prevent local action, the lithanode must be very dense, and this condition may be brought about by pressure and by the use of a *weak* solution of ammonium sulphate. As this retards formation, the patentees add ready-formed peroxide to the lithanode material in various ways, to render the process of formation more easy. They also prefer to coat the plates, especially the grey one, with peroxide electrolytically before applying the lithanode mixture.—E. T.

An Improvement in Filaments for Incandescent Electric Lamps. R. Langhans, Berlin, Germany. Eng. Pat. 3082, February 26, 1890. 4d.

THE filaments, whether of metal or carbon, are coated, as in Eng. Pat. 2438 of 1888, with silicon or boron, which may, however, be obtained in other ways than those described in that patent. Such materials as silicon-tetramethyl, &c., which in a liquid or gaseous form are capable of being decomposed by heat, may be used, the process being analogous to that of "flashing" as ordinarily understood. Solid silicon or boron compounds may be used, if dissolved in a suitable liquid. The boron and silicon coatings possess very high electric conductivity and are very little acted on by oxygen; very high evacuation is not therefore necessary.—E. T.

Improvements in the Process of and Means for the Manufacture of Cellulose with the Aid of the Electric Current. C. Kellner, Vienna, Austria. Eng. Pat. 5420, April 9, 1890. 8d.

See under XIX., page 62.

Improvements in and Relating to Electric Batteries. H. H. Lake, London. From the Crosby Electric Company, New York, U.S.A. Eng. Pat. 15,182, September 30, 1890. 6d.

A CYLINDER of zinc fits tightly in a jar of pasteboard, wood fibre, or other material, coated with shellac on the outside and paraffin and ozokerite on the inside. A carbon rod is placed in the centre of the jar, the bottom of the latter being covered with a pad of felt or other absorbent material, damped with dilute sulphuric acid or other excitant. The space between the carbon and zinc is filled up with sawdust, or such packing material, mixed with sal-ammoniac or other dry excitant.—E. T.

Report on Animal Products, &c. Report of the Central Laboratory of the Italian Customs Department, 1886—1889, 441—465.

BUTTER is taxed according as it is fresh or salt, the former paying 12'50 lire, the latter 17'50 lire per quintal. In a recent decree (March 31st, 1890) it was laid down that margarin and oleomargarin made up as butter should be assessed as fresh butter, but that these substances in the crude state should be classified with fats of all sorts.

As regards fats, those of beef and mutton, and vegetable fats extracted from any exotic plants, are free of duty. Lard pays 10 lire per quintal; pressed beef and mutton fats, sold commercially under the name of stearin, pay 12'50 lire, while fatty acids, liquid, at ordinary temperatures, and composed principally of oleic acid, are free, but if solid pay 8 lire. According to the decree mentioned above, distinction is drawn between fatty acids which solidify up to 40°, those solidifying between 40° and 48° classified as chemical products not specified, and those solidifying above 48° classified as stearic acid. The Department is thus frequently called upon to decide between lard and beef or mutton fat, and in the case of a fatty acid, whether it is oleic acid or a commercial stearin.

In the course of remarks, attention is drawn to the adulteration of lard, or beef and mutton fats, with cotton oil, which is carried on to a large extent in America.

Lanolin, used extensively in the preparation of pomades and cosmetics, may be distinguished by the following special characteristics :—(1) It should not lose more than 80 per cent. when heated to 100°; (2) it should not yield ammoniacal fumes when heated with a 3 per cent. soda solution; (3), it should contain only small quantities of free fatty acid.

For the determination of the melting point of commercial stearin in the Custom house, an apparatus recommended consists of a test tube containing the substance to be examined, in which is immersed a thermometer, the whole being enclosed in a flask filled with water at 100°. In a table the values are given for the acidity number, the iodine number, and the oleic acid calculated therefrom, as also the melting points of various samples of stearin. Controversies arise, firstly, as to whether a fatty substance is to be regarded as a fat or as fatty acid; to decide this in the Custom house the following method is recommended, based upon the regulation which permits of the presence of 25 per cent. of free fatty acids in a rancid fat :—The fatty substance is melted until it is free from air bubbles, and then passed into a glass receptacle (consisting of a bulb with a drawn out extremity) up to a certain mark, and to it is added a known

volume of caustic potash of known strength with a few drops of phenolphthalein. Secondly, as to whether a fatty substance is to be regarded as a beef or mutton fat or as lard. The Department remark that a determination of the iodine number is not sufficient, as hitherto supposed, but a microscopical examination is also necessary. Other questions also arise which are more readily decided. Special investigations are being conducted in the Laboratory on the properties of the oil of Ilipé (*Bassia longifolia*). A table is given of samples sent, but fraudulent declarations are apparently not frequent.

Honey and Waxes.—Animal waxes are taxed according to their degree of purification and at a higher rate than vegetable waxes, such as those of carnauba, palm and Japan, &c., which are referred to stearic acid. Mixtures of animal with the vegetable waxes or with stearic acid, spermaceti, &c. are assessed as animal waxes.

When the Department is called upon to decide as to whether any sample of wax is of animal or vegetable origin, or is a mixture, the following determinations are made:—The specific gravity, melting and solidifying points, as also the saponification and acidity numbers. In the latter purpose the methods proposed by Hübl (Benedikt, *Analyse der Fette*, 286) are adopted, an especial stress being laid, upon the ratio between the numbers obtained. An adulteration of resin is readily recognised either by its solubility in alcohol or by the addition of sulphuric acid, when an intense reddish-brown colouration is produced.

Honey of every sort is subject to a duty of 10 lire per quintal, but "rose honey" and all kinds of confectionery containing honey, are classified as "sweetmeats and conserves with sugar."

The table of analytical results of samples sent to the Laboratory do not point to the perpetration of any particular fraud.—V. H. V.

The Composition of Bees-wax. A. and P. Buisine. Bull. Soc. Chim. 1890, 3, 867—873.

The authors have determined the iodine absorption of pure, dry, washed bees-wax, and find that 100 parts of the wax

absorb 8.3—11 parts of iodine, corresponding to 9—12 per cent. of oleic acid. They confirm the results obtained by Hübl and Heibner for the total, free and combined acids. They estimate the alcohols present in the wax by fusing it at 250° with potassium hydrate and potash lime, and measuring the hydrogen evolved. In the residue from this fusion they determine the hydrocarbons by extracting them with suitable solvents.—H. S. P.

The Bleaching of Bees-wax and the Composition of White Wax. A. and P. Buisine. Bull. Soc. Chim. 1890, 4, 465—470.

Bees-wax is most commonly bleached by simple exposure to air. For this purpose it is run into thin layers which are exposed to the air in full daylight. The colouring matter in this way undergoes total oxidation, and, according to circumstances, the wax is completely decolourised in from 10 to 30 days. When thus exposed to air the colour does not gradually and uniformly fade from it, but white spots make their appearance and rapidly spread.

To bleach wax in this manner the action of air and light is necessary; under the direct rays of the sun the bleaching is most rapid. Yellow wax put into a flask through which air circulates, but kept in the dark, does not bleach at all, even if the air is replaced by pure oxygen or by ozone; but under the influence of light the decolourisation is very rapid, especially in ozonised oxygen. Moreover, it is not the heat of the sun that produces this effect, because at a temperature of 60° and in the dark it has been found that ozone does not attack the colouring matter of the wax.

Wax becomes bleached by the sun (but very much more slowly) even in a vacuum or in the presence of inert gases, such as carbon dioxide and nitrogen.

The method adopted by the authors in the examination of bees-wax has already been described by them in a previous paper (see preceding abstract).

The accompanying table made from the analysis of a series of samples of yellow waxes bleached by air shows the limits between which the determinations varied. The results obtained for pure unbleached yellow wax are given for comparison:—

	Melting Point.	Free Acids equivalent to Mgrms. of KOH per 1 Grm. of Wax.	Total Acids equivalent to Mgrms. of KOH per 1 Grm. of Wax.	Iodine absorbed by 100 Parts of Wax.	Volume of Hydrogen at 0 and 760 mm. from 1 Grm. of Wax.	Hydrocarbons from 100 Parts of Wax.
					Ce.	
Pure yellow wax	63—64	19—21	91—95	10—11	53.5—55	13—14
Pure air-bleached wax	63.5—64	20—21	93—100	6—7	51—55	11—12

It is seen that the two points in which bleached wax differs appreciably from yellow wax are the diminution of the quantity of hydrocarbons, and its lower iodine absorption. From this it is evident that in bleaching by air, besides the destruction of the colouring matter which undergoes a total oxidation, the non saturated compounds of the wax (the acids of the oleic series and the non-saturated hydrocarbons) fix oxygen forming saturated compounds not capable of absorbing iodine.

In practice pure wax is never bleached; the bleachers

always add from 3—5 per cent. of tallow. For this there are several reasons, the chief of which is that pure air-bleached wax is too brittle; besides, a small quantity of tallow makes it bleach quicker, and, further, it is the only way of obtaining a perfectly white product. The addition of this amount of tallow is a recognised thing and is not considered an adulteration.

The following table shows the comparative analyses of pure yellow waxes and air-bleached waxes containing from 3—5 per cent. of tallow:—

	Melting Point.	Free Acids equivalent to Mgrms. of KOH per 1 Grm. of Wax.	Total Acids equivalent to Mgrms. of KOH per 1 Grm. of Wax.	Iodine absorbed by 100 Parts of Wax.	Volume of Hydrogen at 0 and 760 mm. from 1 Grm. of Wax.	Hydrocarbons from 100 Parts of Wax.
					Ce.	
Pure yellow waxes	63—64	19—21	91—95	10—11	53.5—55	13—14
Air-bleached waxes with 3.5 per cent. of tallow added	63.5—64	21—23	105—115	6—7	53.5—57	11—12

The air-bleached waxes containing from 3—5 per cent. of tallow differ from pure yellow waxes in their contents of acids, their iodine absorption, and the proportion of hydrocarbons.

The free acids are somewhat increased; the total acids are notably increased. The iodine absorption is much lower than that of yellow waxes, showing that the oleic acid of

the wax disappears at the same time as that of the added tallow. The volume of hydrogen yielded by the action of potash-lime on the wax is increased to only a small extent

in consequence of the formation of a small quantity of oxyoleic acid. The behaviour of tallow alone on exposure to air is shown below:—

—	Melting Point.	Free Acids equivalent to Mgrms. of KOH per 1 Grm. of Tallow.	Total Acids equivalent to Mgrms. of KOH per 1 Grm. of Tallow.	Iodine absorbed by 100 Parts of Tallow.	Volume of Hydrogen at 0° and 760 mm. from 1 Grm. of Tallow.
Fresh tallow.....	47.5	2.75	202	36.01	Cc. 52.5
Fresh tallow exposed to the air for 40 days in a thin layer.....	48.5	1.86	213	27.68	60.4

The results obtained from white waxes of commerce ought always to be within the limits indicated above when the tallow has not been added in an excessive proportion.

These analyses show the influence that tallow has upon the bleaching of the wax; its action depends upon the oleic acid it contains, which, being easily oxidised, facilitates by its oxidation the combustion of the colouring matter, and the more non-saturated compounds there are present, susceptible of fixing oxygen, the more rapid is the bleaching. Spirits of turpentine added in small quantity to the wax has the same effect as tallow.

Other methods of decolourising raw wax may be employed, as, for example: melting the wax in the presence of animal charcoal and filtering; or certain oxidising reagents may be used, such as potassium permanganate, potassium bichromate in an acid solution, or hydrogen peroxide.

Reducing agents, such as sulphurous acid and sulphites, do not act upon the colouring matter of bees-wax. Chlorine cannot be used as it combines with the wax similarly to iodine, and alters its properties completely.

The following table shows the composition of wax bleached by different methods. It will be seen from it that wax decolourised by potassium permanganate, by potassium bichromate, &c., varies greatly; the proportion of acids that the products contain after treatment depends upon how far the oxidation has been carried.

The results given in this paper enable one to judge whether a sample of commercial white wax is pure, and, to a certain point, to decide by what process it has been bleached.

—	Melting Point.	Free Acids equivalent to Mgrms. of KOH per 1 Grm. of Wax.	Total Acids equivalent to Mgrms. of KOH per 1 Grm. of Wax.	Iodine absorbed by 100 Parts of Wax.	Volume of Hydrogen at 0° and 760 mm. from 1 Grm. of Wax.	Hydrocarbons from 100 parts of Wax.

A New or Improved Process for Producing Hard Potash and Similar Soap from Solid or Liquid Fats. H. Enrich, Frankfurt-on-the-Main, Germany. Eng. Pat. 11,292, July 13, 1889. *Id.*

THE process consists in gradually adding concentrated solutions of alkalis to the fatty or oleaginous material while the latter is heated to a temperature of from 110°—130° C. The whole of the fat and the whole of the lye undergo saponification, and no elimination of secondary lye or glycerin is said to take place.—O. H.

Improvements in Soap. W. G. Little, Bexley. Eng. Pat. 14,914, September 21, 1889. *Id.*

THE patentee incorporates soap, when in the form of paste, with sawdust, ground wood, or wood pulp.—C. F. C.

Improvements in the Separation of Fats from Emulsions. C. D. Hellstrom, Stockholm, Sweden. Eng. Pat. 9062, June 11, 1890. 6d.

"In an emulsion the particles of fat are in the form of spheres of very different sizes; for example, in milk, the largest are of about 20 times greater volume than the smallest. Each sphere of fat is surrounded with a zone of the surrounding liquid. The zone lessens the flotation of the spheres of fat in proportion to the size of the latter, so that the small spheres no longer possess any flotation; these cannot be separated by centrifugal action alone, except when the larger spheres draw them in a manner with them. The path of the larger spheres through the mass under the influence of centrifugal action will be an unbroken line. When, however, the mass also receives a motion parallel to the axis, the larger spheres which possess flotation will on account of their small density receive a relative motion in an axial direction. If the axial motion continually changes its direction the larger spheres will travel in a zigzag course about the line, which, in the absence of axial movement, would have been the path. The larger spheres so travelling will continually collide with the smaller spheres of fat, which on account of the surrounding zones do not take part in the relative motion. The separation of the fat is rendered more complete by this method. As the axial movement in the mass gives rise to pressure, the particles will coalesce and the enlargement of the at first small particles of fat takes place fairly quickly throughout the mass. On the surface this enlargement of the spheres of fat is hastened by the movements originated by the axial motion. In centrifugal action the surface places itself normally to the resultant of the centrifugal force and gravitation; if there be also axial motions the surface tends to place itself normally to the resultant of all three; as, however, the axial motion is variable both as regards amount and direction, the particles on the surface have a wavy motion. This takes place quite symmetrically round the axis, so that a section which is placed perpendicular to the axis will be alternately extended and compressed, and by this means the particles of fat will be made to unite. By each union of two spheres a portion of the liquid which envelopes the spheres will be liberated; the fat, therefore, is more thoroughly freed from liquid than by centrifugal action alone.

"When the temperature of the emulsion is such that the fat is cool, the transition to a firmer state of aggregation is hastened by the repeated variations of pressure; if, for example, milk is treated at a temperature under 23°C . in this way, butter is produced. With continuous inflow and outflow the process is made continuous."

The axial movements may be produced by various arrangements. The annexed drawing gives an example. A is a shaft in bearings C C, driven by means of the pulley D. F is a connecting rod connected at one end with the crank B on the shaft A, and at the other end by means of the pins *a* with the sleeve G on the axle H of the centrifugal machine. *b* and *c* are collars on the axle of the centrifugal machine, by means of which the axle receives movement from the connecting rod. The axle H of the centrifugal machine is set in rotation by means of the pulley J. *d* is a pin in the boss of the pulley J, which pin enters a slot *e* in the axis of the centrifugal machine. Thus the axle H can rotate independently of the axial movement. K K are bearings for the axis of the centrifugal machine. L is the basket of the centrifugal machine, *f* the pipe admitting the emulsion, *g* the outlet for the separated fat. The liquid passes away at the periphery by the pipe *h* and the hole *i*.

Improvements in the Manufacture of Compressed Cakes of Soap. P. H. Newton, London. From the Cheesebrough Manufacturing Company, Brooklyn, U.S.A. Eng. Pat. 9614, June 20, 1890. 6d.

TABLETS of soap produced by the present method of compression are wanting in homogeneity. The soap is cut into blocks of a length less than that of the cakes into which they are converted, and transferred to the die. The first action of the dies in their closing movement is to displace a portion of the soap to fill the end of the dies, and in displacement the soap is so broken up that the subsequent continued compression fails to make it uniform in density with those portions which undergo compression without displacement. According to the present invention the bars of soap are cut and compressed at one operation, whereby the cakes produced are said to be perfectly homogeneous.

—C. F. C.

THE SEPARATION OF FATS FROM EMULSIONS.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

The Painting of Iron. Eng. and Mining J. 1890, 50, 648.

To prevent paint on iron from scaling off in large flakes, the iron surfaces should be washed before any paint is used, and then brushed with hot linseed oil. When the objects are small and bear being warmed, they may be heated, until the linseed oil, with which they are brought in contact, begins to fume, then all the surfaces are carefully brushed with the oil and allowed to cool. They are now ready to take the paint. When the objects are too large, and a warning not to be recommended, the linseed oil must be put on very hot. The thin liquid oil is said to enter into all the pores, remove all moisture and adheres so firmly to the iron that frost, rain, or air cannot effect a separation. To iron surfaces oiled in this manner the paint adheres well. This proceeding is also to be recommended for wood which is exposed to the open air.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

Tanning Woods. S. S. Arnaudon. *Monit. Scient.* 1890, 34, 915—921.

In this paper the author treats of the tanning woods obtained from plants belonging to the natural order *Anacardiaceæ*.

Astronium or *Urundey*.—The plants belonging to this genus reach a considerable size—up to 20 metres in height and 1·5—2 metres in diameter. They occur in Central America, particularly in Paraguay. Several species are known, such as *Astronium juglandifolium*, *A. urundeipao*, *A. fraxinifolium*, and others. They are known locally by such names as *urundey-mi*, *urundey para*, *urundey-pita*, *urundey-herro*, and *urundey-nero*.

Wood of urundey-mi.—The wood of this species is more yellow, and lighter in weight than that of any of the others. A 5 per cent. decoction is brownish-red in colour and deposits a precipitate on cooling. On treating the decoction with various reagents the following results were obtained. Dilute sulphuric and hydrochloric acids gave an orange precipitate. Oxalic acid, the same, mixed with calcium oxalate. Potash and ammonia merely darkened the colour of the extract. Alum gave an orange-yellow precipitate. With lime a large orange-brown precipitate was obtained. Aluminium acetate and stannic chloride gave orange precipitates. Acetate of lead yielded a brown precipitate, turning violet after a time. Sulphate of iron gave a black precipitate. Potassium bichromate turned the colour of the decoction to a maroon shade. Sulphate of quinine and gelatin gave voluminous flocculent brown precipitates. The tanning power of the wood was tested by digesting 5 sq. cm. of hide with 5 grms. of the ground wood and 250 cc. of water for several days. The hide was found to be completely tanned and very little coloured. An extract of the wood acted equally well, but the hide was more coloured by it. In order to estimate the tinctorial power of the wood, various materials were soaked in a decoction of it, exposed to the air and then passed through a bath of potassium bichromate or sulphate of iron. The materials were dyed deep orange-red and black respectively. When sulphate of copper was employed, a dark brown colour was obtained. All the colours were unaltered by sunlight.

Urundey-herro.—The wood of this species is heavier and darker than the preceding. Under a magnifier it appears to consist of gummy layers, incrustated with a brown colouring matter. The decoction is darker than that from *urundey-mi*, and is slightly fluorescent. In other respects it resembles the latter.

Black urundey.—This wood is heavier and darker than the others and yields a larger extract to water. The extract is brownish-red in colour and rapidly tans hide.

Urundey bark.—A decoction of the bark is orange-yellow in colour, and throws down a precipitate on cooling. The extract tans hide more effectually than a decoction of the wood, but the resulting leather is darker in colour. In combination with potassium bichromate, or a salt of iron it may be employed to dye hides and fabrics orange-red or black.

Wood and Leaves of the Molle.—Various plants occurring in Central America bear this name. Those of use in tanning are the *molle a curtir* (*Duraoia latifolia*), the *molle ispiito* (*Duraoia pruroi*), the *aguaribay* (*Schinus molle*), the *molle dulce* or *beber* (*Lithrea gilesii*), and the *molle de Castilla* (*Schinus terebinthifolium*). These plants are all comparatively small, being from 1 to 1·5 metres in height. The leaves, bark, and wood of most of them contain tannin.

Schinopsis Lorentzii Gris, or *Red Quebracho*.—The common Spanish name *quebracho* or *quebracha* signifies "break hatchet," in reference to the great hardness of the wood. The quebracho tree grows to a considerable size. The bark is thick and red and possesses tanning properties. A gum, resembling gum kino, oozes from the bark, and is

also disseminated between the fibres of the wood. The tree abounds in South America, particularly in the sub-tropical regions. The wood has a specific gravity of 1·260, and in contact with cold water imparts a bright orange colour to the latter. With boiling water a dark orange decoction is obtained which deposits on cooling a reddish-orange sediment consisting almost entirely of tannin. The freshly cut wood is bright orange in colour, but on exposure it darkens to a reddish shade. The following reagents give precipitates with a decoction of the wood:—Dilute sulphuric and hydrochloric acids, a bright orange, the liquid above the precipitate being clear. Alum added to an alkaline decoction throws down an orange-red lake. Aluminium acetate, a yellowish precipitate. Stannous chloride, an orange-yellow, and stannic chloride, a darker precipitate. A small quantity of an iron salt gives a blue-black precipitate, whilst an excess of iron salt produces a grey one. Potassium bichromate throws down a voluminous reddish-brown precipitate, copper salts give a greenish precipitate. Acetate of lead throws down a bright precipitate, and in the supernatant liquid basic acetate of lead produces a further precipitate. Aluminium sulphate gives a greyish precipitate.

Quebracho wood contains about 18 per cent of tannin. If the ground wood be exposed to the air for several months, the percentage of tannin diminishes, which appears to be due to a sort of resinification setting in. The extract, concentrated to 30° B., contains 50—56 per cent. of tannin; the dry extract contains over 60 per cent. To tan 100 kilos. of fresh hides, 150 kilos. of wood costing 22·50 francs, are required.

The same quantity of bark was used to tan eight dozen sheep's hides. The time required was 28 days. Instead of 150 kilos. of the wood, 60 kilos. of extract at 30° B. might be employed, costing 31 francs. But as one-third of the tannin is left in the extract, the net cost would be 20·60 francs. In replacing the quebracho wood by sumac, a bale of the latter, costing 20 francs, would be required. The leather produced by means of quebracho wood is, however, greatly superior. It has more body, and is stronger, although the colour is somewhat darker than when sumac is used. Quebracho wood also contains a yellow dye-stuff. Hides and fabrics may be dyed a bright yellow, using as mordant a double salt of tin and ammonia, mixed with potassium bitartrate. Wool and leather have a much greater affinity for the colouring matter than silk or cotton. In conjunction with potassium bichromate, quebracho wood dyes stuffs a fine brown, or a splendid black is obtained by substituting a mixture of ferrous chloride and pyrolignite for the bichromate.

Sumacs.—The leaves of sumac and fustic are already used in tanning. The woods of the following species of *Rhus* contain tannin:—*R. tiphina* (Virginian sumac), *R. glabra*, *R. rhodanthemum*, *R. cotinus*, *R. elegans*, *R. oxyacanthoides*, in appreciable amount. *R. semialata* contains a little less. Probably the following species of *Rhus* also contain tannin:—*R. Tahlense*, *R. atra*, *R. thunbergii*, *R. tomentosa*, *R. lucida*, *R. succedanea*, *R. serratum*, *R. pentaphylla*, *R. japonica*, *R. radicans*, *R. toxicodendron*, *R. viminalis*, &c.—H. T. P.

Report on Gallic and Tannic Acids. Report of the Central Laboratory of the Italian Customs Department, 1886—1889, 293—301.

Under this category are classed powders for tanning, extracts from various barks, tannin, and the like. Gallic and tannic acids are classified as pure and impure, and subject in the first case to a duty of 10 lire per quintal, but in the second are free. It is further laid down that certain extracts or pastes of dye-woods and other colouring matters which may contain a proportion of tannic acid are not to be included in this class. The authors remark that pure tannic acid in the exact sense of the word does not occur in commerce; the so called pure acid contains a greater or less proportion of impurity, which is not, however, injurious for practical purposes. The Department were called upon to decide as to whether a certain extract was to be considered a "tanning extract" or colouring matter, in the

first case being exempt, in the second subject to a duty of 12·50 lire per quintal.

Of the methods proposed for the analysis of tannins, preference is given to those of Lowenthal, modified by Schröder, and of Hammer, improved by Simand. (This Journal, 1888, 528.)

Analyses are given of samples sent to the laboratory; one case, declared as impure tannin, was found to contain 60·59 per cent. of tannin, and was therefore assessed as commercially pure, while two others denominated impure gallic acid were infusions of tannic acid.—V. H. V.

PATENT.

The Production of Sulphate of Ammonia (SO₄NH₄O) from the Nitrogen of Marshy Moors or Meadow Land Moors, and Apparatus therefor. W. L. Wise, London. From H. Grouven, Leipzig, Germany. Eng. Pat. 1136, March 21, 1878. (Second Edition.) 1s. 3d.

See under VII., page 45.

XVI.—SUGAR, STARCH, GUM, Etc.

α- and β-Amyrins. Their Ethers and Bromine Derivatives. A. Vesterberg. Ber. 23, 3186—3190.

THE α- and β-amyrins employed in this research were prepared from "Manilla gum-clone," which was estimated to contain 20—25 per cent. of total amyrins. Of this quantity about two-thirds to three-fourths was α-, and the remainder β-amyrin. As the result of his experiments the author adopts the formula C₃₀H₄₈O for the amyrins. α- and β-amyrin are very much alike, both forming long, silky, flexible needles, fairly soluble in benzene, ether, glacial acetic acid, and hot alcohol, difficultly soluble in cold alcohol and petroleum spirit. α- and β-amyrin require for solution 21·36 and 36·11 parts of absolute alcohol respectively. α-amyrin melts at 181—181·5 °C., β-amyrin at 193—194 °C. They are both dextro-rotatory.

Dissolved in benzene—

α-amyrin	(α) _D = + 91·59°
β-amyrin	(α) _D = + 99·81

The amyrins are most probably secondary alcohols. By the action of phosphorus pentachloride they are converted into dextro-rotatory *amyrilenes*, C₃₀H₄₈. Phosphorus pentoxide converts α-amyrin into *lento-α-amyrilene*, which is isomeric with the above. The amyrin acetates are readily soluble in chloroform and are both dextro-rotatory.

α-amyrin acetate forms large tables, melting point, 221° C.

$$(\alpha)_D = + 77.$$

β amyrin acetate forms long prismatic crystals, melting point, 236 °C. (α)_D = + 78·6.

By oxidation with chromic acid they yield *acetymyrin* acetates, C₃₀H₄₂O₇.C₂H₃O₂.

Bromo-α-amyrin, C₃₀H₄₅Br.OH. Melting point, 177—178 °C. (α)_D = + 72·8. Fairly soluble in ether and benzene.

Bromo-α-amyrin acetate, C₃₀H₄₃Br.C₂H₃O₂. Separates from benzene in hexagonal plates or flat prisms containing benzene. Melting point, about 268 °C.

Bromo-β-amyrin was not obtained in the crystalline state. Its solution solidified on cooling to a colourless jelly. Melting point, about 182—186 °C.

Bromo-β-amyrin acetate forms prismatic crystals, melting at 238 °C. Fairly soluble in petroleum spirit. The corresponding compound is almost insoluble in petroleum

spirit. This difference in solubility may be utilised to separate α- and β-amyrin. For this purpose the mixture of the acetates is brominated, and the resulting compound is simply boiled with petroleum spirit.—H. T. P.

Studies on Starch. K. Zulkowski. Ber. 23, 3295—3297.

THE author, referring to Scheibler and Mittelmeier's paper bearing the above title (this Journal 1890, 1140—1141), points out that his own researches on starch have not been mentioned by them in their historical account of the chemistry of starch. The results obtained by the author are briefly as follows:—Starch is dissolved by hot glycerol, being converted into soluble starch, which by further heating is completely broken down. The author obtained not only erythro- and achroo-dextrins, but a series of bodies increasingly soluble in alcohol. One of them, indeed, was soluble in a mixture of absolute alcohol and ether, from which solution it could be precipitated by barium hydrate.

These various bodies were separated by means of their different solubilities, &c.; but it was found exceedingly difficult to remove the last traces of glycerol from the various products, possibly owing to the formation of glycerides.—H. T. P.

Saccharine Bodies in Fungi. E. Bourquelot. Compt. Rend. 111, 578—580.

THE author has previously pointed out that in order to estimate the saccharine matter in a fungus at a given period of its growth it is necessary to arrest the life of the cryptogam at that period. Further, he has proved in the cases of *Lactarius piperatus* and *Boletus aurantiacus* that the vegetative processes continue for some hours after gathering, as is evidenced by the conversion of trehalose into mannite. In the present paper the author gives the results of analyses of various fungi at different periods of their existence. After pointing out the difficulty of distinguishing in certain species young from old fungi, the author defines the adult age as that at which the heads open out and the spores form and commence to fall down. In the case of all the experiments made by the author the fungus was treated with boiling water immediately after gathering.

As the results of experiments on 13 different species, 12 species were found to contain only trehalose in the young state. At a more advanced age these species contained either mannite only or else both mannite and trehalose at the same time.

In the single case of *Amanita mappa* mannite only was found in the young state of the plant. Finally, in two species, *Boletus aurantiacus* and *Hypholoma fasciculare*, after desiccation at a low temperature the trehalose was found to be replaced by mannite. The author is inclined to believe there is some connexion between these sugar changes and the formation of the spores. In some cases there is further complication from the fact that the amount of glucose is increased, or even in certain instances that glucose is actually produced.—A. J. K.

Report on Sugars. Report of the Central Laboratory of the Italian Customs Department, 1886—1889, 130—192.

Cane Sugar.—A description is at first given of the various types of sugars and saccharin substances imported into the Kingdom. For a long time past the Custom house tariff divided imported sugars into two classes, namely, those of a whiter colour than that of the type 20 of the Dutch scale, which were regarded as refined, and those of a darker shade, considered as impure sugars. This distinction was further confirmed by a reciprocal treaty with Austria-Hungary in 1878. But the protection which the State intended to grant to native refinery became the object of considerable fraud, as sugars, imported as crude sugars, were coloured with a little lamp-black or molasses, or more rarely aniline-yellow, sophistications practised under the very eyes of the Custom house officials, who were powerless in the matter. The

Department was therefore called upon to determine if it were possible to maintain the distinction between the two classes, adopting some criterion other than colour. At the outset it was shown that samples of the same standard according to the Dutch system contained most variable proportions of sugar, and that there was no relation between colour and percentage or rotatory power. A large number of analyses of samples from various countries and importers are given in confirmation of this view; analyses are also given of samples of crude sugars in relation to the drawback. The results are discussed with especial reference to the various proposals made by different refining firms to the Commission of inquiry into the revision of the tariff. The conclusions drawn from the discussion are (1) that the systems of classification by colour is most unjust and unreliable; (2) that the greater part of the sugar imported in the first half of the year 1887 had a polarisation value greater than 95 (French scale); (3) that samples of a less value were colonial sugars, intended for the more needy classes, and formed a small fraction of the total importation; (4) that the objections raised by Signor Depretis in the report of 1887 against the saccharimeter system are ill-founded, especially as other governments, viz., those of France, Holland, and the United States have adopted the system.

Other Sugars.—Milk sugar is referred to the first class, but grape sugar and maltose to the second; sugars from fruits and invert sugar are included under the head of grape sugar. The Department fear that attempts will be made to introduce invert sugar as starch syrup.

The Drawback.—In 1886 the Government conceded to the sugar refiners a drawback upon the import duty of crude sugars to be refined in the country and subsequently exported. Certain questions arose as to the interpretation of the regulations, especially with regard to the meaning of the word "richness" as the effective quantity of saccharose, or the quantity which could be obtained from a crude sugar, and secondly, whether the loss of $1\frac{1}{2}$ per cent. on purification was to be calculated on the crude product or on the yield. The Department decided that the concession might be made in terms of the crude sugar, and interpreted the word "richness" to mean the theoretical yield, which is obtained by subtracting from the polarisation value double the weight of the salts and the amount of reducing sugar, but without deducting the loss on refining. The methods adopted for the analysis of crude sugar as practised in the Central Laboratory and in the Provincial Laboratory of Genoa are given in full, as also those for the determination of raffinose in beetroot sugar. As regards the latter the method based upon its conversion into mucic acid is not accurate within 0.29 per cent., but by the polariscope the value may be determined by means of the following formula, $R = \frac{A - Z}{1.57}$, in which R is the percentage of raffinose, A the polarisation value, and Z the percentage of saccharose determined by Clerget's inversion formula.

It appears, however, that a large joint stock company were dissatisfied with the regulations of the drawback, and the matter was again referred to the authors of the report. It was then decided that "the yield from a crude sugar after refining shall be calculated by subtracting from the polarisation value three times the weight of sulphated ash, and twice the weight of the glucose when equal to or less than 2 per cent., but if more, then once the weight only. From the number thus obtained, which represents the theoretical yield, the $1\frac{1}{2}$ per cent. loss shall be deducted, and on this number the tax shall be paid, no account being taken of decimals less than 0.5." Finally the regulations proposed by the Sugar Bounty Convention held in London in 1888 are given in full.

Glucose.—The tariff distinguishes between solid glucose which pays 66 lire per quintal, and liquid glucose, paying 50 lire; starch syrup pays 40 lire. By a law, February 12, 1888, glucose, which had not been subjected previously to a manufacture tax, pays 30 lire. The methods adopted for the analysis are described.

The process used for the detection of saccharin proposed by Girard are given fully, and it is pointed out that they

are sufficiently delicate to prevent any chance of sophistication. Another method proposed, which gives satisfactory results, is as follows:—An ethereal or petroleum extract is evaporated after addition of a certain quantity of nitric acid to dryness in a water-bath; a small fragment of caustic potash added, and the mass moistened with two or three drops of water. A colouration is produced varying from blue to reddish purple.

The tariff report refers to the category of starch syrup extracts of malt and barley, which have been neither concentrated nor dried; but if dried so as to resemble burnt syrups they are classed under sweetmeats. A sample declared as liquid glucose was found to be a concentrated malt extract, while another labelled as "Malz extract Gesundheits bier" was referred to as medicinal drugs not specified.—V. H. V.

XVII.—BREWING, WINES, SPIRITS, Etc.

The Treatment and Storage of Beer. A. Hartley. Trans. Institute of Brewing, 4, 3.—51.

Cask Selection.—Whether the casks are previously examined by the coopers or not, they should always be passed by the best available man in the cellar prior to racking. In large breweries there must, of course, be several passers-in, and it is never advisable to allow one man to pass very many casks at a time. The sense of smell becomes deadened, and, from sheer inability, he will be sure to pass many that he would have rejected at an earlier period of his work.

A very prevalent trouble during the warmer months is the tendency to acidity or sharpness. These sharp casks are fatal to the stability even of quick-running beers, such casks should be soaked in a hot solution of salt and soda. After emptying and rinsing, they should be well treated with sulphurous acid, with the object of destroying the acid ferments in the pores of the timber. After rinsing with sulphurous acid, the casks should be left some few hours tightly corked and bunged; they can then be steamed out ready for use. Cask sharpness is often intensified by allowing the empties to lie about exposed to the heat of the sun, when the film of residual beer is very prone to acidification, owing to the influence of air and high temperature combined.

Racking.—This is done either direct from the primary fermenting vessel, or from the dropping-square, or from the settling- or racking-back. If cleansing in a secondary vessel be deemed advisable, it can be best accomplished in the dropping-square, which retains its natural covering of yeast. The transference of finished beer from vessel to vessel is most prejudicial, owing to the oxidation to which it is exposed. But upon the dropping system the beer is in more or less active fermentation when the change takes place, and it is at any rate supersaturated with gas which reduces the absorption of air. Racking-backs are in many plants essential as a means of collecting the contents of several primary fermenting vessels. They are most convenient for blending purposes. It is hardly necessary to remark that the beer should be led into these backs at the bottom, so that foaming and consequent oxidation may be as much as possible prevented. From whatever class of vessel the casks are filled, it is important to avoid absorption of air. Racking with the ordinary hose or stocking is most objectionable, on account of the foaming which occurs by reason of the delivery end floating on the surface of the rising beer. To obviate this, it is a good plan to attach a tinned metal thimble to the end of the hose, of sufficient weight to keep it in position close to the bottom of the cask, the length of the hose being adjusted with this object.

Cask Hops.—They have four principal influences, which are exerted upon the flavour and aroma of the beer, and upon its stability, condition, and clarification. They affect condition in two ways. They undoubtedly carry with them

into the beer certain ferment organisms, which must to some extent influence the secondary fermentation. It is probable that in this respect their influence is not always a desirable one, and that some of those unpleasant flavours that are noticeable in dry-hopped beers might be traced to these organisms. It would be a great improvement if the hops could be washed, or in some way sterilised before they are used. But the cask hops have another and very direct effect upon secondary fermentation, which is due to the increased agitation of the beer whenever the casks are moved. The influence of motion on fermentation is an accepted fact, and is probably chiefly due to the bringing of fresh volumes of wort or beer into direct contact with the yeast cells, and to the dispersing of the exhausted media, and retarding products of fermentation which surround them.

With regard to the influence of cask hops upon clarification, this is rather a mechanical than a chemical one. There are many who hold closely to the idea that clarification depends upon the hop tannic acid. The author maintains that the action of finings is independent of this body. The influence of the hops is of chief importance in promoting the spontaneous brightness of the beer. They afford a large amount of surface attraction whereby the semi-soluble and floating particles in the beer are removed from suspension. In the author's opinion they help to keep the coagulated gelatin in a compact mass, and so prevent it from breaking up into lumps which so often constitutes a trouble with running beers that are not dry-hopped.

Secondary Fermentation and Condition.—The secondary or cask fermentation is of the highest importance in the production of our best qualities of ales. The aim of the brewer now is to accelerate the cask fermentation as much as possible, and to bring his ales into ripe condition with the least possible delay. Healthy cask fermentation is now known to depend upon the action of secondary yeasts, of which there are several types and mixtures, giving rise to different characteristics and flavours. During the slow and prolonged fermentation in cask, the palate of the beer is greatly modified by the products of the secondary yeasts, and the formation of various ethers which give that peculiar vinous character to stored beers. Secondary fermentation is also of the utmost importance in regard to the clarifying capacity of beers. It is often found that beers which are more or less dull after fining when fresh, readily become brilliant after a few weeks' storage in cask. Apart from flavour and brilliancy, cask fermentation is essential to that briskness or gassiness usually expressed by the term condition, and which is due principally to the action of secondary and bottom ferments upon the malto-dextrin in the beer. These ferments have the power, not possessed by the primary types, of breaking down the malto-dextrin into maltose, which is then fermented. Consequently in natural cask fermentation malto-dextrin plays a principal part. This body not only imparts fullness and head, but also, by its gradual decomposition, promotes the steady evolution of gas, causing the beers to retain their life on tap.

The addition of syrup or priming has two principal effects—namely, the imparting of a lusciousness to running beers, and the accelerating of those cask changes upon which the flavour and briskness of stored beers depends. It is often dangerous to employ priming in running ales during summer, especially if they are insufficiently clean, as the primary yeast cells are rendered too active, and unhealthy cask fret is promoted. In winter, quick running beers are usually much improved by priming, if the yeast is in healthy condition. If there is a preponderance of unsuitable ferments, it is unwise to stimulate their action, and when beers are a little out of health priming has usually to be dropped. The two principal objects may be attained by two different classes of syrup. Lusciousness by a solution of invert sugar, which also acts as a stimulant to condition; and rapid condition or briskness, where sweetness is an objection, by glucose priming.

The action of the secondary yeasts in breaking down the malto-dextrin, in beer, may be supplemented by the employment of a cold water extract of malt. So powerful is the diastase thus obtained that half a pound of grist has a distinct influence on 100 barrels of beer. This quantity should be steeped in two pints of water for some six hours

and then strained. The diastase liquor is afterwards added to the racking-back, and well roused in. If there is no racking-back, and no opportunity of adding it to a large bulk of beer, it can be mixed with several gallons of beer, and the correct proportion added to each cask. With a sufficiency of malto-dextrin in his worts, the brewer thus has a further means of determining the condition of his beers. If intended for lengthy storage he will wait for the gradual degradation of the body by the cask ferments. If he requires rapid condition he will employ cold malt extract at racking. The practice of adding malt-flour as a priming to stouts is a very old one, but its true significance has only been recently discovered. It acts similarly to the cold water extract of malt, but the latter is decidedly preferable, especially for ales, owing to the absence of husky particles.

Beers that are hopped should always be well rolled every day for about a week before they are topped up and shived down, so that the hops may be thoroughly soaked, and the maximum of absorption attained. After shiving, they should again be rolled, daily if possible, for at least a week before they are stacked away.

Cleansing in Trade Casks.—By cleansing is meant the elimination of the residual primary yeast before the casks are shived or bunged. The beers are racked a day or two earlier than is customary on the ordinary system, and the temperature should not be cut down quite so low. They are racked into cask with a little life left in them, so that the primary yeast may work out as much as possible through the bung hole. The casks need slight topping up once or twice a day for a day or so, and it is remarkable what an improvement this slight amount of cleansing makes in the flavour and eventual brilliancy of beers so treated. This system also gives very good results with pale ales, with which cleanness is so highly important. If these ales are thus worked it becomes necessary to postpone the introduction of the hops until the process of cleansing is finished. This may be several days. A little ale has to be syphoned out to make room for them, and it is more convenient to wet them first. After the addition of the hops, the casks should be bunged and rolled occasionally for a few days longer before they are topped up and shived. In breweries where it is difficult to attain satisfactory cleanness at racking, this system is recommended, as it is undoubtedly prejudicial for the beers to be closed down with any large percentage of primary yeast remaining in suspension.

Preparation for Bottling.—Preliminary cleanness is very important in the case of beers intended for bottling. Unless sufficient brightness at racking has been secured, the process just referred to is very beneficial. Indeed, it may be improved upon by bunging down and rolling the casks well every day prior to being topped up. The agitation of rolling enhances the assimilative capacity of the yeast, and the elimination of those bodies that cause undue yeast growth in bottle. In the production of beers for bottling it is most important that there should be a minimum of matter that either comes out of solution during the bottle fermentation or stimulates unnecessary yeast reproduction. This essential cleanness can only be satisfactorily accomplished by the aid of sound and vigorous secondary fermentation in cask. After shiving, beers for this purpose should be rolled with more than ordinary assiduity, with a view of obtaining, if possible, spontaneous clarification, the very best proof of natural cleanness. But it often happens that beers which are comparatively clean and have passed through their secondary fermentation, will not drop sufficiently brilliant for bottling in the time required. Recourse must then be had to fining. But it is a mistake to suppose that beers are fit for bottling simply because they go bright with finings, unless they have undergone cask fermentation. New beers are certain to throw a heavy deposit, and are very likely to be cloudy in bottle. There is a somewhat popular idea that beers should be flattened before they are bottled. The excess of gas must be let off through porous pegs, but the greatest care should be taken to exclude any air, which is fatal to brilliancy. If fining has to be resorted to, the smallest efficient quantity should be added, and the casks should be allowed to settle for at least a week.

Temperature.—For pale ales and stock beers a moderate one of about 55° F., when it can be maintained, is the most satisfactory. Temperature has a decided influence upon the flavours developed during cask fermentation, in the same way as during primary fermentation. Cellars that receive running beers may be somewhat warmer than those used for stock and pale ales; but it is not advisable to allow the temperature to much exceed that which may be expected in the cellars of the consumer, for in winter there is danger of chilling, after fining, which causes lack of brilliancy. This effect of temperature reduction is the result of bodies, that are only just soluble at higher temperatures, coming out of solution. The cleaner the beers the less likely this trouble. The heat of the beers at racking ought, as a rule, to be a few degrees lower than the likely temperature of the store. Stock beers may well be several degrees below, as the rise in heat will cause expansion, and so prevent ingress of air through crevices in the casks.

Fining and Sampling.—The use of old beer for this purpose is unsound both in theory in practice. The main point to be observed in the manufacture of white finings is sufficiently lengthy steeping. Good finings cannot be made in a hurry. The glass should be steeped for at least a month before it is passed through the finest sieve. It is a good plan to put the steep through a coarse sieve as soon as the glass is soft enough, as further softening is much hastened. If a little water is added daily, and the mixture is kept well roused up, it is usually ready for coarse sieving in about a fortnight. In regard to quantities and proportions, much of course depends on the quality of the glass, which may be very variable. With good Penang leaf a gallon and a half of sulphurous acid, and one pound of tartaric acid may be used for every seven pounds of glass. These quantities should make two barrels of white finings with the daily additions of water made up to a definite strength. This can be tested by the viscosity tester, the time occupied by a definite volume of finings in passing through a small hole giving the comparison required. A definite working standard can thus be easily fixed.

Colour.—The question of colour is in many breweries a troublesome one. Standard sample bottles are very useful, and may be made with orange aniline dye and caramel mixed. These bottles must be made up with half methylated spirits to prevent settlement and loss of colour.

Yeast-Pressing.—Where there is a good proportion of stout and porter, there is no trouble in working off pressings at a good profit. It is most important that yeast should not be allowed to get stale, and in some smaller breweries this is the tendency. The most satisfactory plan is, of course, to press every day, and certainly it should not be done less often than twice a week. In summer, if pressings have to be kept some few days before blending, salicylic acid is the best thing to use as a preservative. Sulphites give an unpleasant flavour and smell.

Waste.—Waste is a most unsatisfactory thing to deal with. When, however, there is a demand for aged beers, there is not any trouble in getting rid of it at a good profit; but in many breweries it is impossible to dispose of the entire waste of a public trade by blending, without prejudicing the character of the beer. It often pays best to allow so much per barrel, and to refuse to receive the waste. When they can be worked up, it is usual to vat them, and if this is done, the more hops that are added to the vat the better.

Returns.—The working up of returns also requires great attention. There are four different kinds: acid, flat, turbid, and casky. The working off of flat returns is the easiest of all. They can be added direct to running beers. Casky returns are practically impossible to deal with, and are best turned down the drain. Some forms of turbidity are very difficult to overcome. They are improved very often by intermixture with acid ones, but when much is returned on this account, it is not wise to blend souers with them, as the acidity may increase, and so enhance the difficulty of blending with mild-flavoured ales. Hopping, as suggested in the case of waste, is the best treatment, combined with rolling when the quantity is not sufficient for vatting. Time usually brings brightness, and until this has been tried they

should not be worked off. Acid returns need very careful working off. They may, of course, be neutralised, but this treatment requires considerable skill, and is not, in my opinion, very satisfactory. They may be heavily treated with salicylic acid, to prevent them from becoming worse. The returns of each day should be regularly tasted and sorted, and the casks should be marked for special treatment according to the complaint: if sour, for soaking, if casky, for the cooper. All little lots should be turned into odd-and-end casks, no ullages should be left on hand, and everything should be done to release as many of the trade casks as possible. If the quantity is large enough to employ a vat, the returns should be pumped over at the earliest opportunity. Everything that is fit to use up at once should be immediately blended off. Acid and turbid returns must remain in cask or vat until practically bright. By daily supervision of the returns, it is possible to greatly facilitate working up, and to avoid a great deal of unnecessary trouble and loss.

Preservatives.—With good malts, sound mashing systems, and thorough cleanliness, preservatives are seldom required, but with doubtful materials, the judicious employment of antiseptics is advantageous. If, however, they are added in excess, much more harm than good accrues, on account of their retarding influence on cask condition, which is so important in regard to stability. The basis of most preservatives is some sulphite, or mixture of sulphites and salicylic acid. Salicylic acid is very useful in many cases, especially for running beers brewed from low-class materials. But for ales that are required to come into early condition, it is not satisfactory. There is an impression that the antiseptic power of the sulphites depends upon their affinity for oxygen, and that they owe their action to the absorption of oxygen existing in the beer. But the change from the sulphite to the sulphate is practically a very slow process, and there is a large excess of oxygen in the beer that cannot be attracted by the small amount of preservative employed; their antiseptic action must, therefore, be due to some more direct influence upon the organism. The sulphates and chlorides present in brewing liquors are, of course, very important natural preservatives, and the additions that are often made to the liquor are very useful, both directly and indirectly, in promoting the stability of the finished beers. But of all preservatives, cleanliness is the best, and without it stability and character are unattainable.

Cleanliness.—In regard to the cleanliness of racking-rooms and cellars, much depends on their construction. Cement, concrete, or granolithic flooring, and glazed tile walls are, of course, the nearest to perfection. The surfaces of these departments ought all to be constructed so as to admit of thorough washing with a hose. Plain brick walls and old timber should be repeatedly washed with a mixture of freshly-burned lime and chloride of lime, the latter at the rate of about one-sixth. For the flushing out of drains, chloride of lime is very useful. It is a good plan to mix some with cold water in an old cask at the rate of about four pounds per barrel. Add one pint of sulphuric acid, previously diluted in a wooden bucket with cold water. Allow the cask to remain for some few hours tightly bunged, and then empty down the drain. All wooden vessels, such as troughs and shoots, should be frequently scalded out, and occasionally painted over with sulphite of lime. Beer mains should have steam connexions, and they should be steamed out every time they are used. India-rubber hoses are somewhat difficult to keep clean. They must be flushed with cold liquor after use, and then hung up to dry. It is a bad plan to coil them up when damp. Hot liquor cannot be used for hoses without doing harm, and this is a great disadvantage. They may occasionally be charged with a weak solution of permanganate of potash without injury. All racking-stockings should be scalded out every night, and hung up to dry, and a strict rule should be made of having all filling and topping-up cans, and buckets, well washed every evening, and set in a rack to drain. For the cleansing of wooden vessels, such as vats and racking-backs, powdered pumice-stone, laid on wet upon the brush, as suggested by Aldous, is very useful. Slate vessels can also be cleaned with it. For vessels of either material an occasional coating of sulphite of lime is beneficial.—J. H.

PATENTS.

Improvements in the Manufacture of Degerminated, Flaked, Boiled, and Torrefied Maize to be used for Brewing and Distilling Purposes, and also as a Prepared and Cooked Food, and in Apparatus employed therein. J. White, Belfast. Eng. Pat. 17,434, November 2, 1889. *Sd.*

THE maize is first thoroughly cleaned in the usual way. The smaller grains, amounting to one-third of the entire bulk, are sifted out and the remaining larger grains then thoroughly moistened in order to toughen the germs and make them more readily detachable from the "grits" or starchy parts of the grains. The damp maize containing about 25 per cent. of water is passed between a roller, making about 500 revolutions per minute, and a fixed segment, the curvature of which is the same as that of the roller. The roller may have a diameter of 20–30 inches. The fixed segment and roller are provided with concave under-cut flutes or grooves, the edges of the flutes pointing upwards and downwards respectively. The flutes of the roll have a lead of about 4 inches. The distance between the edges of adjoining flutes is about one-sixth of an inch in the case of the roll, and about one-eighth of an inch in the case of the segment. By means of this apparatus the maize is degerminated more thoroughly, and less fine meal is produced; whilst a greater proportion of husk is left on the "grits," thus leading to better drainage in the mash-tun. The mixture of grits and germs is freed from flour by sifting, the germs being subsequently removed by treatment in any suitable washer. The degerminated grits are cooked by boiling or any other known means, a suitable yeast-food being added at this stage. The grits are then partially dried and passed between rolls under great pressure, the rolls revolving at the relative speeds of four and five respectively. By this means the flakes are made thinner and larger. Finally the flakes are torrefied, when they are fit for use.

—H. T. P.

Apparatus for Use in Rectifying Spirits and other Matters. B. Hoff and J. Frommel, Galicia, Austria. Eng. Pat. 20,434, December 19, 1889. *Sd.*

THE apparatus consists of a series of columns, each divided into a number of compartments by dome-shaped partitions, communication between the various chambers being made by a short pipe or hole in each dome. The top of each column is connected by a pipe to the base of the next column in series. The lower part of each chamber is joined to a tube which carries off the condensed matters into a common main, or otherwise. In some or all of the chambers of each column there is a stack of condensing blocks placed on a perforated false bottom. These blocks are made of some smooth non-porous substance, and may be of spheroidal, cylindrical, polygonal, wedge-shaped, or other suitable pattern. They are pierced in various directions, the perforations being either straight or curved, the object being to increase the area of the condensing surface as much as possible without impairing its smoothness. This apparatus is said to require no artificial cooling, the air surrounding the vessels being sufficient for this purpose. The most efficient refining action is obtained when the perforations in the blocks cross one another, like the meshes of a net. Of course, the blocks and perforations are made of sufficient size to avoid capillary action between the adjacent surfaces.—H. T. P.

Improved Method of and Apparatus for Obtaining an Accelerated Fermentation and Producing Sparkling Drinks. E. Edwards, London. From F. Hofmeister, Munich, Germany. Eng. Pat. 678, January 11, 1890. *Sd.*

THE invention consists in spreading the ferment used over a large surface immersed in the liquid to be fermented. For this purpose the fermenting vessel is provided with a large number of diaphragms, bars, bands, or strips, preferably consisting of some pure tasteless fabric. In order to take up as little vat space as possible the supports

are made very thin, and the surfaces are placed in an inclined position, and in some cases perforated to allow of the ready escape of the carbonic acid. Descriptions and drawings of several forms of fermenting vessels constructed on the above principle are given. The fermentation of wine, beer, &c., is started as follows: The ferment-supporting surfaces are sprinkled with old must, beer, &c., and the tun is closed and a current of air aspirated through the apparatus for 36 hours. The must, wort or other liquid is then run into the tun, when fermentation soon commences. Or, the arrangement of surfaces may be at once placed in a fermenting liquid, with the result that fermentation will be considerably accelerated. In order to produce sparkling drinks the tun and its ferment-carriers are placed in a strong vessel provided with a lid, which is fitted with a pressure gauge, tap, and man-hole. After fermentation the liquid may be drawn off through a tap at the bottom, which communicates with the fermenting vat. Two forms of the above apparatus are described. According to temperature and other factors, a pressure of 4–5 atmospheres is developed in a period of 1–6 days. If fermentation has been carried on slowly (3–6 days) the wine may be drawn off quite bright, provided the apparatus has been kept at rest.

The use of ferment-bearing surfaces is of great importance to breweries. Fermentation can be carried on at a lower temperature than usual, and since fermentation goes on rapidly, a smaller number of vessels will suffice. The invention will also be of great value to distilleries, leading to a considerable economy in time. The losses which usually occur owing to the passage of unfermented matter into the wash, and to acid fermentations produced at the expense of alcohol, will be entirely prevented by the rapid fermentations at comparatively low temperatures obtainable by the use of this system. The working efficiency of the apparatus increases with its age; only the deposits on the surfaces should be withdrawn about every two months.—H. T. P.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A.)—CHEMISTRY OF FOOD.

Report on Confectionery and Preserves with Sugar and Honey. Report of the Central Laboratory of the Italian Customs Department, 1886–1889, 192–281.

ALL substances belonging to the category are subject to a duty of 100 lire per quintal. Thus no analyses of imported goods are required, but in the case of exported goods a drawback is allowed for the sugar used in the manufacture, and the Administration reserve the right of determining the amount of sugar so as to assess the goods. But questions have arisen with regard to tamarinds, tea-biscuits, and farina, of which tamarinds, containing less than 32 per cent. of saccharin matter, pay 7 lire per quintal, but, if more, they are assessed as confectionery; tea-biscuits pay 15 lire per quintal (general duty), and 42 lire (conventional duty with Switzerland), provided that they do not contain more than 18 per cent. of sugar; farina, which is defined as "alimentary substances for infants, composed of the same material as tea-biscuits," provided that the sugar, naturally present and added, does not exceed 40 per cent., pays as biscuits, but if more, as confectionery.

As regards the drawback on exported goods a table is given of the various rebatements allowed by the different regulations since the year 1859 on superior and inferior kinds of candied fruits, plain and flavoured chocolate, condensed milk, mustard, vermouth, preserved chestnuts, and citrate of magnesia.

The general criteria on which the rebatement is based are also discussed, and recent alterations notified.

The method for the detection and analysis of various sugars, when separate and mixed, are also fully discussed, and the instructions laid down by the German Custom-house regulations are also given.

Results are also quoted of analyses of tamarinds, farina, candied fruits, and tea-biscuits, which were made in the Laboratory; short observations are made on certain especial samples.

Various methods for the analysis of condensed milks are discussed, and a note is given by A. Bignamini on a method for determining cane sugar invert and milk sugars when present in the same liquid. The method is briefly as follows: (1) A portion of the liquid is heated with a slight excess of Fehling's solution until the reduction due to the milk and invert sugar is complete; (2), the filtrate from the precipitate is acidified, the excess of copper removed by barium hydrate: the cane sugar is then inverted and the cupric oxide reducing power again determined; (3), in another portion equal to that taken in (1), the cane and milk sugars are first inverted and the cupric oxide reducing power determined. Then from the known cupric oxide reducing powers of the invert and milk sugars the factors for the requisite simultaneous operations are determined. Experience in the Laboratory has, however, shown that milk sugar is not inverted by hydrochloric acid under the conditions usually adopted.

In tables analytical results are given of samples of condensed milks exported from July 1886 to March 1888, when the drawback allowed was 78·50 lire per quintal, and from March 1888 to July 1889, with a drawback of 90 lire. In the first period the calculated total of cane sugar was 250·034,520 kilos., corresponding to rebatement of 196,277·10 lire, and in the second period 307,631·03 kilos., with a rebatement of 276,867·91 lire.

The regulations of the drawback on the so-called citrate of magnesia are the same as those of condensed milks; analyses of exported samples are given. The calculated amount of cane sugar in the former of the above periods was 2,112·97 kilos., corresponding to a rebatement of 1,658·68 lire, and in the latter 6,299·48 kilos., with rebatement of 5,669·53 lire.—V. H. V.

Improvements in the Manufacture of Degerminated, Flaked, Boiled, and Torrefied Maize to be used for Brewing and Distilling Purposes, and also as a Prepared and Cooked Food, and in Apparatus employed therein. J. White, Belfast. Eng. Pat. 17,434, November 2, 1889. 8d.

See under XVII., preceding page.

Improvements in the Preparation of Malted Sweet Foods, Confections, and the like. W. Paterson, Glasgow. Eng. Pat. 6338, April 25, 1890. 6d.

A THICK syrup of any suitable sugar or mixture of sugars is carefully neutralised, for which purpose bicarbonate of soda is most convenient. The syrup is then concentrated until its boiling point reaches 325° F., or until a suitable consistency is obtained. The boiled sugar is poured out on a slab and allowed to cool to 167°—185° F., when a quantity of malt extract, previously heated to 170° F. on a water-bath, is thoroughly mixed with it. 20—30 per cent. of malt extract is the most suitable amount to use, and on no account must the temperature be allowed to exceed 185° F. Any colouring or flavouring agent added at this stage must be previously neutralised. In fact, the patentee lays great stress on the perfect neutrality of all the materials employed. The mixture is finally moulded into any suitable shape and preserved in well-corked bottles.—H. T. P.

Improvements in the Method of Treating, Preserving, and Packing Raw Flesh Meat, Beef, Veal, Mutton, Lamb, Pork, and the Stomachs, Bellies, Feet, and Tails of Cows, Bulls, Oxen, Calves, Sheep, Lambs, and Swine. E. Eardley, J. G. Cochrane, and E. Weild, Manchester. Eng. Pat. 12,065, August 1, 1890. 6d.

AFTER slaughtering and quartering the animals, they are stitched in canvas, allowed "to set," dipped in an antiseptic solution of borax, boric acid, permanganate of potash or other material, then plunged in or covered with sweet warm fat, lard, tallow, paraffin wax, or other suitable composition. Stomachs, bellies, and feet, &c., after being thoroughly washed and scalded, are dried in a hydro-extractor and then treated as above, except that they are not covered with canvas. Tails are allowed to cool and then treated like the stomachs, &c., omitting the scalding. The barrels and packing cases are painted with antiseptic solution, then with the lard or other composition as above.—J. M. H. M.

Improved Apparatus for Filtering Sewage and other Liquids. W. Birch, Manchester. Eng. Pat. 4732, March 26, 1890. 8d.

AN endless filtering band travelling through guide rollers traverses the bottom of a trough into which the liquid to be filtered is conducted by a pipe and spreader. Underneath the band is a grid in which are small flush guide-rollers, and small rollers are also employed to keep down the upper surface of the band. On emerging from the trough, covered with sludge, the band is conducted over a concave support against which it is brushed or squeezed at intervals by a small roller having a backward and forward motion as well as one of rotation. The band is by this means freed from sludge and surplus water.—J. M. H. M.

(C.)—DISINFECTANTS.

PATENTS.

Improvements in Disinfectants and Antiseptics, and in Disinfectant and Antiseptic Soaps. M. Hargreaves, Preston. Eng. Pat. 18,460, November 19, 1889. 4d.

CHLOROPHENOLS and similar compounds are formed by treating carbolic and cresylic acids, vegetable tar, and the like with chlorine gas. Or the alkali salts of these chlorophenols are formed directly by the action of bleaching powder or alkaline hypochlorites upon the phenols in presence of water.

The chlorophenols or their salts are mixed with absorbents such as carbonate of lime (as obtained from causticising soda), sawdust, sand, &c., to form disinfecting powders, and with soap to form disinfectant soaps.—J. M. H. M.

An Improved Compound for Disinfecting and other Purposes. H. H. Lake, London. From W. F. Limes, Philadelphia, U.S.A. Eng. Pat. 12,323, August 6, 1890. 4d.

A DISINFECTANT and moth preventive composed of oil of camphor, "naphthaline," and caustic soda. The camphor oil is boiled with soda and the "soap" mixed with "naphthaline" and moulded into cakes, lozenges, &c.

XIX.—PAPER, PASTEBOARD, Etc.

Colloidal Cellulose. Papier Zeitung, 1890, 778.

A substance bearing the name of colloidal cellulose has been prepared by treating dried cellulose with sulphuric acid of 50° B. It is a gelatinous translucent mass which retains its condition for an indefinite time, even in the presence of an excess of acid, provided no rise of temperature take place. At 100° C. it is quickly converted into dextrin. The pure substance can be freed from acid by treatment with water and alcohol and drying at a low temperature. It then gives with water a milky fluid which can be filtered and suffers no change even after the lapse of several days, or on boiling. It is somewhat more soluble in hot than in cold water. Its solution appears orange-yellow by transmitted light, and a 100 mm. layer is dextro-rotatory to the extent of 0.75°. The solution is precipitated by the addition of small quantities of sulphuric acid, nitric acid, sodium chloride, and lead acetate; large quantities of alcohol produce the same effect. It does not become coloured on the addition of iodine, nor does it reduce cupric solutions. The residue left on evaporation is in the form of a shining film which swells up and dissolves in water. Prolonged treatment with sulphuric acid of 55° B. or short exposure to acid of 60° B., renders it insoluble in water, dextrin being formed at the same time. Well-dried colloidal cellulose undergoes nitration in much the same way as the ordinary variety, and the product is only distinguishable from the substance before nitration by being somewhat less translucent.

These properties of colloidal cellulose elucidate various facts observed in connexion with ordinary parchment paper. Certain weak parchment papers yield soluble cellulose on treatment with boiling water, whereas the stronger sorts are not attacked; doubtless a stronger acid is used in the preparation of the latter, whereby the soluble cellulose at first formed is reconverted into the insoluble variety. Parchment paper, therefore, appears to consist of a network of ordinary cellulose filled in with colloidal cellulose. This is borne out by the fact that filter paper treated on both sides with soluble cellulose and rolled, much resembles the product as usually manufactured.—B. B.

PATENTS.

Improvements in or Connected with Breaking and Beating Engines used in making Paper Pulp. J. H. Annandale, Bolton. Eng. Pat. 14,558, September 16, 1889. 6d.

The invention is applicable to breaking and beating engines, in which the operating roll works in a casing entirely closed, excepting the inlet and discharge openings. It consists in discharging the pulp from the engine against a head or back pressure by extending a discharge pipe from

the outlet up some feet higher than the machine, the pulp being delivered from the top of such pipe. The height of this outlet is adjustable so as to secure the best effect under various conditions both as regards materials operated upon and the rates of feed, &c., of the roll.—C. F. C.

Improvements in Boilers for the Manufacture of Sulphate Cellulose and in the Method of Treating the Same. C. Kellner, Vienna, Austria. Eng. Pat. 4959, March 29, 1890. 8d.

The improved boiler is provided with jackets composed of a number of separate parts, easily removable when it is desired to inspect the boiler. The space between boiler and jacket is filled with a liquid of high boiling point, which is heated to and maintained at a temperature somewhat higher than that in the boiler or digester which contains the wood and the bisulphite solution. The specification describes and illustrates a stationary and a revolving digester filled in the above manner.

The inventor also claims an internal lining consisting of plates of tempered glass; these may be fixed by means of a mixture of equal parts of Portland cement and sand, or of a mixture of quartz powder, glass powder, fire-tile powder, brick powder, carbonate of lime, phosphate of lime, and soluble glass.—C. F. C.

Process of Modifying the Properties of Fibres used in the Manufacture of Paper. C. Kellner, Vienna, Austria. Eng. Pat. 5128, April 2, 1890. 6d.

The inventor claims that cotton and cotton-like fibrous materials are modified so as to resemble linen by boiling under pressure (3 atmos.) with weak solutions of certain acid salts, such as the bisulphites of the alkalis or sulphate of alumina. On the other hand linen-like fibrous materials are modified to resemble cotton by boiling under pressure with weak alkaline solutions. The inventor also claims that these modifications are produced by saturating the fibrous materials with solutions of salts, such as nitrates or sulphates, and causing the pulp so impregnated to pass between two metallic cylinders connected with the poles of an electric current generator.—C. F. C.

Improvements in the Process of and Means for the Manufacture of Cellulose with the Aid of the Electric Current. C. Kellner, Vienna, Austria. Eng. Pat. 5420, April 9, 1890. 8d.

The present invention is a simplification of Eng. Pat. 15,912 of 1886 (this Journal, 1888, 132), for the same purpose, in that it dispenses with the aid of heat and with

MANUFACTURE OF CELLULOSE BY THE AID OF ELECTROLYSIS.

the employment of closed vessels. The reduction of wood to cellulose is effected by treatment in a suitable apparatus with the products of the electrolysis of certain metallic chlorides. The disposition of the parts, *i.e.*, decomposing vessels and electrolyser, is shown in the accompanying figure. The wood, in large pieces, is charged into the middle of the vessel K. The decomposing liquid is carried from the electrolyser B, through the pipe D, into the vessel *k'*, concentric with K. In the bottom of K is an agitator which causes a circulation of liquid, and continuously removes the cellulose disintegrated from the surface of the wood. The liquid carrying the suspended cellulose overflows into the annular casings *k*¹, through siphon pipes *m* into revolving conical sieve drums M, from the wider end of which the cellulose is discharged in the form of pulp, while the liquid passes through the sides of the drums into the gutters *m'*, and thence through pipes E into the recombining tank *a*. *n* is a small steam pipe for keeping the liquid about the ordinary temperature during cold weather, while *n'* communicates with the atmosphere.

—C. F. C.

Improvements in the Manufacture of Coloured Paper. J. H. Carpenter, Chicago, and C. E. O'Hara, New York, U.S.A. Eng. Pat. 6343, April 25, 1890. 4d.

THE patentees claim the process of manufacturing coloured paper, which consists in applying colouring matter to the pulp while on the wire of the machine, the result being to produce shaded and clouded tints either in one or a mixture of several colours, an endless variety of colour effects being so obtained.—C. F. C.

A New or Improved Absorbent Writing Paper. P. White-side, Preston. Eng. Pat. 6458, April 28, 1890. 4d.

THE invention consists "in making the paper with a sufficiently hard and smooth surface for comfortable writing, but the process of calendering the paper is not used to so great an extent as is the case in the highly-glazed non-absorbent papers."—C. F. C.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Rose-Oil. W. Markownikoff. Ber. **23**, 3191.

THE author has investigated the nature of Bulgarian rose-oil. The results obtained are as follows:—The steareptene which separates from the oil melts at 36.5° C., and has all the properties of a paraffin. It is perfectly odourless and has no influence on the commercial value of the oil. The elæoptene consists of a mixture of two bodies, $C_{10}H_{18}O$ and $C_{10}H_{16}O$, of which only one, forming the bulk of rose-oil, possesses an alcoholic nature.—H. T. P.

Cytisin. A. Partheil. Ber. **23**, 3201—3203.

THE author recommends the following process for the preparation of cytisin, which occurs in the seeds of *Cytisus laburnum*. The coarsely-powdered seeds are extracted with alcohol containing hydrochloric acid. The alcohol is distilled off, and the residue dissolved in water and filtered through a wet paper in order to separate the fatty oil. The filtrate is treated with acetate of lead, which removes the greater part of the colouring matter. The filtrate from this is rendered alkaline with potash, and shaken out with amyl alcohol. From the amyl alcohol, dilute hydrochloric acid removes the alkaloid, and the solution thus obtained yields the chloride (still highly coloured) on evaporation. Cold absolute alcohol removes almost the whole of the colouring matter from the solid salt, and by subsequent repeated crystallisation from water the salt is obtained in well-formed, colourless, transparent crystals. The platinum double salt, $C_{11}H_{14}N_2O \cdot H_2PtCl_6$, forms fine golden yellow needles. When heated it is decomposed without previous melting. It is easily soluble in water. The gold double salt, $C_{11}H_{14}N_2O \cdot H_2AuCl_4$, is slightly soluble in water, and melts with decomposition at 212—213° C.—H. T. P.

Isocinchonine. O. Hesse. Annalen, **260**, 213—226.

ISOCINCHONINE, $C_{19}H_{22}N_2O$, can be easily prepared by dissolving commercial cinchonine sulphate (30 grms.) or the free base in dilute (from 1:5 up to 10) sulphuric acid (150 grms.), and keeping the solution for 24 hours at the ordinary temperature, or heating it at 60—80° for six hours. The solution is then poured into cold water, excess of soda carefully added, and the product extracted with a large volume of ether; after evaporating a considerable quantity of the ether, the residual solution is kept for some time at the ordinary temperature, whereon crystals are deposited. The ethereal solution is then decanted and evaporated completely to obtain the isocinchonine, which quickly solidifies; the crystalline product is pressed and then purified by recrystallisation from ether or by converting it into the crystalline hydrochloride, and decomposing this salt with soda. It melts at 125°, is readily soluble in acids and most neutral solvents except water, and is levo-rotatory. It forms with acids both neutral and acid salts which, as a rule, crystallise well. The hydrochloride—

loses its water of crystallisation at 140°—150°, and melts at 201°.

The crystalline deposit referred to above is always obtained, although only in very small quantities, when commercial neutral cinchonine sulphate is employed, it consists principally of hydrocinchonine and apocinchonine. These two compounds can be separated from one another by dissolving the mixture in concentrated sulphuric acid, and heating the solution at 80°—100° for a few hours, or by dissolving it in dilute sulphuric acid and adding potassium permanganate drop by drop until a permanent colouration is produced. If the freshly precipitated alkaloids are then treated with ether the apocinchonine passes for the most part into solution, whilst most of the hydrocinchonine remains undissolved, and can be obtained in a perfectly pure condition by means of its sulphate. It is possible, therefore, to isolate the hydrocinchonine present in commercial cinchonine sulphate without the aid of potassium permanganate. Even if the salt or base employed in the preparation of isocinchonine is free from hydrocinchonine, when it is treated with sulphuric acid and the solution kept for 24 hours, a small quantity of a crystalline deposit is always obtained from the ethereal solution in the manner described above. In such cases, however, it consists principally of apocinchonine, an alkaloid which is not converted into isocinchonine under these conditions.—F. S. K.

The Manufacture of Quinine in Madras. Board of Trade J. January 1891, 99—102.

THE Administration Report of the Government Cinchona Department, Nilgiris, for the year 1889—90, contains an article on the manufacture of quinine at Naduvatam, in the province of Madras.

From this article it would appear that the manufacture of the sulphate of quinine upon a small scale was commenced about the end of June 1889, when many experiments were made for the purpose of finding out the most rapid and economical methods of extracting, first, the alkaloids from the bark; secondly, of obtaining the pure sulphate of quinine from the alkaloids; and also of training the native workmen in the business. All this took some time, and it was not till the beginning of October that the men were

sufficiently advanced to admit of the manufacture being begun upon a large scale. One of the chief difficulties to be contended with at first was the want of proper vats, and the designing and making of these all meant delay. The most serious matter, however, was the enormous loss of fusel oil which was experienced, the only costly ingredient needed for the extraction of the alkaloids from the bark; but this loss, though still considerable, has been greatly reduced by distilling the bark after the alkaloids have been extracted from it. The still required for this purpose was not put up till February, and the manufacture of quinine had to be suspended till that time. At this date it would have been possible to begin making quinine at the rate of 60 lb. or thereabouts per week, as a fresh supply of fusel oil had been just received from the Government of Bengal, pending the arrival of a fresh supply from England. Unfortunately, all calculations were upset by the outbreak of the Russian influenza epidemic; every one of the workmen who had been educated with so much care during the former months, being scared by the reports which they had heard respecting the disease, fled to their homes in Mysore, and fresh men had therefore to be drilled; it was only towards the middle of May that it became possible to recommence work on anything like a proper scale. It had been calculated that a steam-engine of six-horse power would be sufficient for working up the produce of three vats, and that these three vats would turn out 90 lb. of crude sulphate of quinine a week, and about 80 lb. of the pure sulphate or 4,000 lb. of quinine during the year. It has been found, however, that the engine, which is insufficient when heated by wood to warm up more than three of the pans simultaneously, still less is it able to heat up the still while the pans are being heated. To obviate the delay caused by having to use the engine separately for the pans and still, it will be necessary to obtain an additional boiler with a fire-box of larger dimensions than the present engine is fitted up with. The number of vats also must be doubled, and it is hoped, when these are fixed, that if nothing further untoward happens, the full amount of 4,000 lb. of quinine will be made during the present year, notwithstanding that so much time has been already lost.

The following is a detailed description of the methods adopted in extracting the alkaloids from the bark and of extracting the quinine from the alkaloids: 1st. The bark used is a mixture of the branch stem and root of *Cinchona officinalis*, or the crown bark, and which has the following alkaloidal value:—

Quinine	3.02
Cinchonidine	1.01
Quinidine	0.14
Cinchonine	0.24
Amorphous	0.30
Total	4.71
Sulphate of quinine	4.06

The bark is ground up by a Carter's disintegrator, which is fitted with screens the apertures in which are the $\frac{1}{16}$ th part of an inch in width. The powder is then passed through a separator, which has a mesh of 64 strands to the inch. The fine powder which passes through the scalper is that which is used in the factory for the manufacture of quinine. The coarse powder which will not pass through the scalper is put a second time through the disintegrator.

Two hundred pounds of the powdered bark are placed in a cylindrical vat 6 ft. deep and 3 ft. in diameter, and to the powder is added 100 gallons of water in which there has been dissolved 14 lb. of solid caustic soda. There are also added 120 gallons of paraffin and fusel oil in the proportion of 4 parts of paraffin to 1 part of fusel oil, or 96 gallons of paraffin to 24 gallons of fusel oil. The mixture is then stirred by means of paddles, which are arranged on a central spindle after the fashion of a screw, so as to raise the heavier water and mix it completely with the lighter oils. The stirring is carried on for three hours, and the mixture is then allowed to stand overnight. In the morning the oils which have separated from the water and bark are removed by means of a tap which is placed at the junction of the water and the oil. The oil is then carried to the

agitating casks, and to it is added water sufficiently acidulated with sulphuric acid to dissolve the alkaloids which are held in solution by the oil. The oils are washed with the acid water, by means of paddles, for 10 minutes, and then allowed to settle, when the acidulated water is drawn off by means of taps placed at the bottom of the casks. Some more water, not acidulated, is again added to the oils, and the washing is repeated twice. All the water which has been used to wash the oils is then removed to a separator, that is, a tall, conical tub with a tap at the bottom. The water, which always contains a quantity of oils and other impurities, is allowed to stand for half an hour, or other convenient period, and then run off through the tap. By this means the acid water, which contains all the alkaloids, is received in a much purer state than when taken direct from the agitating casks. The acid liquor is then filtered through charcoal and removed to tubs, where it is stored till a sufficient amount has been accumulated to fill the steam pans. The oil, which has been washed by the acid water, is then put back again into the vat and again stirred up with the bark, after which it is allowed to settle for another night, when it is drawn off and treated in the same manner as has been described above. The acid water containing the alkaloids is removed to the steam pans, each of which has a capacity of 50 gallons. Forty gallons of the acid liquor is poured into each pan and heated up to boiling point, when a handful of charcoal is thrown in, and the liquor neutralised by means of caustic soda. After the liquor has been allowed to boil (water boils at Naduvatam at 94° C.) for a quarter of an hour or so, it is filtered into cooling pans, when the greater part of the sulphate of quinine crystallises out; but it also contains 16.5 per cent. of cinchonidine. All the other alkaloids remain in the solution. The crystals the next day are filtered from the liquor, and as much of the liquor as possible is squeezed out by a screw press. The crystals are then removed to the hot room and there thoroughly dried. These are called crude crystals. To the liquor which remains behind, caustic soda is added in a sufficiency to precipitate the remaining alkaloids, and these are then removed for future treatment, when any quinine which they may contain is afterwards extracted. The crude crystals, after they have been dried, are powdered up and re-dissolved in boiling water. The solution is boiled for about a quarter of an hour with some charcoal, and is made very faintly acid; it is then passed twice through double filters into the cooling pans, where the "pure" sulphate of quinine crystallises out, containing about 4 per cent. of cinchonidine. The crystals are filtered from the liquor, and are allowed to drain as much as possible, after which they are placed upon some bibulous paper, on square blocks of plaster of Paris, 1 foot square by 1½ inches thick. The plaster of Paris absorbs rapidly a great deal of the water which the crystals hold; after this the crystals are placed on fresh filtering paper and put upon calico trays, which are removed to the shelves in the hot room, where the temperature is kept at from 15 to 20 degrees above that of the atmosphere. As the lumps of crystals dry they are broken up by forks, and when sufficiently dried, they are removed to the store-room, and the quinine is then ready for packing.

The result obtained from working up a rather large batch will give a rough idea of what is the cost of extracting the quinine from the bark.

From 6,000 lb. of bark there were obtained 227 lb. of sulphate of quinine out of a possible 243 lb., the cost of the chemicals used was—

	Rs.	s.	p.
(1.) 120 lb. of solid caustic soda and acid	23	0	0
(2.) 90 gallons of oil	110	0	0
(3.) Cost of fuel	10	0	0
(4.) Labour	84	0	0
(5.) Interest on building and plant at 10 per cent.	62	0	0
	289	0	0
(6.) Value of bark	3,626	12	0
	3,915	12	0
Value of quinine, at Rs. 17 4 s. per lb.,	3,915	12	0

Bromine. Eng. and Mining J. 1891, 51, 42.

THE bromine industry in the United States was commenced in 1846 by Dr. David Alter, at Freeport, Pa. He continued the business until 1856, but from that time until 1866 no bromine was made in this country. In the latter year the manufacture was resumed at Freeport, and was also begun at Tarentum, Pa., but these works were abandoned again in 1871 and 1874 respectively, and no bromine has been made in either place since.

Works were begun at Canal Dover, O., in 1871, which have continued in operation to the present time. The districts in which bromine is now commercially produced are Pomeroy and the Tuscarawas Valley, in Ohio, Western Pennsylvania, West Virginia, and Michigan. Of these, the Pomeroy and West Virginia regions are the most important.

Bromine is a valuable by-product of the salt industry, occurring in the form of bromides in the bittern. It is prepared from the latter by the addition of sulphuric acid, forming hydrobromic acid, and an oxidising agent—potassium chlorate or manganese binoxide.

The proportion between the bromides and salt differs in different localities; at Canal Dover, in the Tuscarawas Valley, O., from 1877 to 1887, both years inclusive, there were produced 222,669 lb. of bromine and 259,350 barrels of salt, or about 6 lb. of bromine to 7 barrels of salt. In the Pomeroy district the proportion was 1 lb. of bromine to 2 barrels of salt.

More than two-thirds of all the bromine made is used in the manufacture of sodium and potassium bromide for medicinal purposes and photography, while the remainder is used in the colour industry. Attention is now directed to the great efficiency and value of bromine as a disinfectant.

The production in the United States in 1882 was 250,000 lb.; in 1883, it was 301,100 lb.; in 1884, 281,100; in 1885, 310,000. In the early part of the last year, the

price of bromine had fallen to 25 cents per lb., when a combination of all the producers, the National Bromine Company, was formed, and the entire product of the country pooled and sold by one agency. Owing to this combination the price rose steadily from 25 cents to 30 cents in April and to 33 cents before the close of the year.

It was in that year, also, that Michigan first began the manufacture of bromine. At Midland, Midland County, an isolated system of wells yields bittern containing 4·2 per cent. bromine, which is now worked, and produces about one-eighth of the entire product of the country. Prior to this attempts to work Michigan brines had been unsuccessful, bromides being present in too small amount.

In 1886 the production amounted to 428,334 lb.

In May 1887, many of the bromine manufacturers ceased operations temporarily on account of the dullness of the trade and accumulations of stock, but the production for the year amounted to 199,087 lb. The average price was held at 31 cents. The same price continued in 1888, in which year the product increased to 307,386 lb.

The use of bromine as a disinfectant assumed a more important output in 1889 than ever before in this country, 6,800 lb. being used at Johnstown after the flood.

The production of bromine for the year 1889 is estimated to have been 250,000 lb., valued at 92,500 dols., three-fifths of this amount coming from the Ohio and West Virginia region.

The price, which was controlled by the combination of producers, was further increased, and, in 1889, averaged from 37 to 38 cents per lb.

In 1890 the estimated production of bromine in the United States has been as follows:—Michigan, 40,000 lb.; Pennsylvania, 70,000 lb.; Ohio and West Virginia, 200,000 lb.; total, 310,000 lb.; valued at 147,250 dols. The price remained steady at from 37 to 38 cents per lb. during the year.

PRODUCT OF BROMINE IN THE UNITED STATES, 1883 TO 1890, INCLUSIVE.

The consumption of pyrolusite in the manufacture of this amount of bromine is estimated at from 400,000 to 500,000 lb., from 1½ to 2 lb. of pyrolusite being required for each pound of bromine produced. The binoxide of manganese is used as the oxidising agent in the manufacture of bromine by nearly all the producers of the United States with the exception of those in Michigan. The high percentage of calcium chloride in the salines of the latter State makes potassium chlorate preferable as the oxidising agent, since it requires less sulphuric acid and thus avoids the heavy precipitate of calcium sulphate.

During the calendar year 1886, 44,189 lb. of bromine, valued at 12,008 dols.; and in 1887, 66,307 lb., valued at 16,216 dols., were imported into the country. There have been no other importations before or since, so far as known.

PATENT.

Improvements in Processes and Apparatus for the Preparation of an Extract of Tea, and in the Utilisation of the By-products. E. Sonstadt, Cheshunt. Eng. Pat. 20,182, December 16, 1889. *Sd.*

In this invention the tea to be extracted is placed in a digester of conical form, provided with a moveable perforated

false bottom, and communicating by means of a siphon tube with another vessel used as a boiler and placed at a lower level. A supplementary boiler is also added at a higher level, from which water is run into the digester. In order to ensure the better extraction of the tea-leaves the digester is provided with a rod, sliding through a stuffing box, and provided with spokes; and through the lid of the digester a cohobating apparatus is passed connected with small chambers charged with wool, which serve to condense the aroma. The tea is introduced into the digester and hot water run in from the higher boiler, and a current of steam from the lower boiler. When the extraction is complete the latter is shut off and the infusion sucked into the lower boiler, from whence it is run into an evaporator.

The liquid is then concentrated until a sample taken from it hardens on cooling; during the process it is best to keep the mixture in agitation. Part of the wool on which the aroma is condensed is stored up with lump sugar in a closed vessel when some of the aroma is abstracted; the rest of the wool is placed in a mixer with sugar, and the whole moistened with water or "aroma-water." The aromatised sugars can be expressed from the wool and stored in suitable receptacles; the wool is washed and used over again. The more or less dried tea infusion is mixed with the "aromatised sugar," and the whole heated to 100°

in a closed vessel provided with a mechanical agitator, which is worked until it moves smoothly without resistance. After partial cooling the plastic mass is rolled and cut into convenient shapes. The extract may be used for making a "cup of tea," or for the purposes of confectionery; the spent tea-leaves from the digester are compressed and made into blocks to be disposed of as manure; or they may be carbonised in a closed retort to obtain tea-charcoal and tea-tar, which contains ammonia, other nitrogen compounds, acetic acid and other products.—V. H. V.

Action of Borax in the Alkaline Developers. P. Mercier. Compt. Rend. **111**, 644—645.

BORAX, although it has an alkaline reaction, acts as a retarder when mixed with pyrogallol or catechol, doubtless because, as Lambert has shown, it combines with polyhydric phenols to form energetic conjugated acids. No similar reaction takes place, however, with quinol, resorcinol, "eikonogen," or hydroxylamine hydrochloride, and with these compounds borax acts as an excellent accelerator. A solution of two parts of borax in 100 parts of water with two parts of quinol or "eikonogen," gives very good results.—C. H. B.

Reversal of the Negative Photographic Image by Thiocarbamides. J. Waterhouse. Phot. News, 1890, 727—728, 743—744, and 804.

PHENYLTHIOCARBAMIDE added in very small quantity to the ordinary "eikonogen" developer converts the negative image more or less completely into a positive image, even when the plate has received a normal or even an under-exposure. No similar result is obtained with pyrogallol, quinol, or ferrous oxalate developers. A large proportion of phenylthiocarbamide prevents reversal; 12 to 15 parts of the saturated solution (0.1 per cent.) in 100 parts of eikonogen developer will give the best results. A small quantity of potassium bromide, and in some cases traces of ammonia, seem to aid reversal. Over-exposure prevents reversal. A preliminary oxidising bath of nitric acid (5 per cent.) is useful in copying work, and the use of a bath of cupric bromide before fixing also gives clearer lights. Potassium dichromate does not answer so well as a preliminary oxidiser as nitric acid.

Allyl-thiocarbamide, though less regular in its action, produces even stronger effects of reversal with eikonogen, with pyrogallol containing sulphite, and with quinol containing sulphite and sodium carbonate.

Thiocarbamide in small quantity produces reversal with the eikonogen developer, and also with a quinol developer on Wratten's "ordinary" plates, and seems to be a very powerful accelerator with both developers, but is much less regular in its action than the substituted thiocarbamides.

Carbamide produces no reversal, and hence it would follow that the sulphur plays an important part.

All the thiocarbamides in presence of alkali darken silver haloid salts which have not been exposed to light. In absence of alkali they have no effect, except in the case of allyl-thiocarbamide, which dissolves and seems to combine with the silver haloids.—C. H. B.

PATENTS.

Improvements in Photography. E. H. Farmer, London. Eng. Pat. 17,773, November 7, 1889. 4d.

WHEN dichromates or similar reagents are brought into contact with silver surrounded by gelatin or other colloid, the latter is rendered insoluble to an extent depending on the proportion of silver present. Gelatino-bromide plates are prepared in the ordinary manner except that no hardening material is added, and are exposed and developed in the ordinary manner, preferably with the ferrous oxalate developer. The plate is then immersed in a 20 per cent. solution of ammonium dichromate for about a minute, washed and dried. It can then be used in the same manner as an ordinary chromated film, i.e. etching on copper, production of a Woodburytype mould, direct printing, as in collotype, or for the production of an image in fatty ink which can be transferred to a lithographic stone. The dichromate may be placed in the film or in the developer, but the method described is preferred.—C. H. B.

Improvements in the Method for Producing Intense Light by Magnesium or by other Glowing Materials. J. W. C. Schirm, Berlin, Germany. Eng. Pat. 11,784, July 28, 1890. 8d.

See under H., page 38.

Improvements in or Relating to the "Dusting-on" Process of Producing Pictures by Photography. G. W. Wood, Gatehead-on-Tyne. Eng. Pat. 13,191, August 22, 1890. 4d.

THE sensitive preparation is spread on a surface of ferrotype, vulcanite, or other black or dark coloured material, dried, and exposed under a negative. The process is carried out in the ordinary manner, but the material used for dusting-on is some lustrous substance such as the white, gold or other light-coloured bronze-powders, or powdered aluminium, magnesium, zinc, tin, silver or other suitable metal or alloy. Any other white or nearly white powder may be used, but substances with a metallic lustre give the most brilliant images. Silver precipitated from a solution of silver nitrate by an acidified mixture of ferrous and ferric sulphates gives good results. A sheet of plain glass or other transparent medium may be used as a support and is afterwards backed with black varnish or black paper.

This method has the advantage of giving positives from negatives.—C. H. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

On Precautionary Regulations during the Preparation of Nitroglycerol. F. Scheiding. Zeits. f. angew. Chem. 1890, 609—613.

THE author first suggests that the mixing of the acids should be made in a vessel provided with a cover and chimney for conveying the acid fumes out of the building. The mixing can be effected by means of compressed air, and the cover prevents any of the acids from being thrown out of the vessel. Montejus should be made of cast or wrought iron, preferably not lined with lead. The cast iron withstands the action of the acid better than the wrought iron but is liable sometimes to crack, especially when the air-cock is opened. This cock should therefore be placed outside of the building or separated from the Montejus by a wall, and the Montejus should stand clear of everything so that any leak could easily be observed. In the next

operation which properly may be called dangerous, viz., the nitration of the glycerin, rise of temperature which might lead to explosion may be caused by impure glycerin or the accidental admixture of water. The chemical examination of the glycerin is therefore essential.

The nitrating vessel must be made of thick lead and stand clear on all sides in a well lighted building, yet not exposed to the direct rays of the sun. The contents of the nitrating vessel should be kept cool by several separate coils of thick leaden pipe through which cold water passes. In order to prevent any water from escaping into the acid mixture should one of the worms be damaged during the operation, the cooling water should flow from a higher lying vessel and discharge into a lower lying tank. The cooling worm would thus act as a syphon and draw some of the acid and nitroglycerin mixture into the lower tank, where its presence would be recognised by the turbidity produced, or by means of litmus paper. The agitating or stirring is best effected by compressed air, and the workman should always ascertain by means of a manometer whether there is sufficient air pressure before commencing the nitration. In order that no water may be carried over with the air, a condensation box should be fitted at the lowest point of the air pipe. The nitrating vessel must be provided with a cover or hood and chimney which will convey the acid fumes out through the roof. The whole apparatus stands over a large tank containing water, into which the whole contents of the nitrating vessel can be promptly discharged through a large earthenware cock, should the temperature rise to 40° C.

The floor of this building in certain districts consists of sand, in others of clay. The author prefers a clay floor slightly sloping towards a gutter in the middle which passes underneath the door. The floor should be kept always damp and covered with sawdust, and the place where the men stand covered with a soft mat. The mat should be washed twice a week, and the sawdust renewed once a week and the removed sweepings burned.

The author suggests the erection of one or two shelter-huts in which one or two workers could take refuge when an explosion threatened, and be protected from falling pieces. An alarm horn should be hung in the shelter-hut by which a warning signal could be given for the whole factory. As explosions have been caused in other buildings by debris falling through the roof, the author advises that the roofs of the buildings in which nitroglycerin or dynamite are present should be provided with a strong double lining. The intervening space would also keep the building cooler in summer and warmer in winter. An electric bell should be near the nitrating apparatus, by which a signal could be sent to the laboratory in the event of anything unusual occurring during the operation. The plug of the discharge cock should be carefully examined before each operation to see that it is quite free from any grit or frozen nitroglycerin.

For conducting the nitroglycerin and waste acids through the mound surrounding the building a brick channel thickly covered with tar is recommended, just sufficiently wide to take an open leaden gutter, through which a leaden pipe can be pushed. This pipe can be daily cleansed by rinsing first with concentrated sulphuric acid and then with water.

The author considers the combination of the nitrating apparatus with the separator in one building as injudicious. The separator should be provided with a perforated pipe for compressed air, that in the event of heating taking place, which often occurs only at separate spots, the mixture could be agitated and the danger possibly avoided. It should also have electric thermometers which would ring a bell when a certain temperature was reached. The separator should also have a hood with chimney passing through the roof. Outside of the mound surrounding the separator house there should be a pipe for compressed air with a cock by means of which the agitation of the liquid in the separator could be started should the workmen have fled from the building on signs of danger without starting the air agitator. Should the bells in connexion with the thermometers cease ringing the building can safely be re-entered. An essential condition of safety is that daily all the apparatus should be carefully examined to see if they are in proper working order. After the nitroglycerin has passed to the washing house

the most danger is passed. There the greatest cleanliness should be observed and care taken that no wash-water, which always contains some nitroglycerin, is splashed about. The nitroglycerin must be washed quite free from acid. (This Journal, 1890, 265 and 476.)—W. M.

The Analysis of Dynamite. F. Scheiding. Zeits. f. angew. Chem. 1890, 614—615.

See under XXIII., page 70.

PATENT.

A Process and Apparatus for the Manufacture of Nitrated Starch. W. Schueckher, Vienna, Austria. Eng. Pat. 14,625, September 16, 1890. 6d.

STARCH, preferably potato starch, is dried at 100° C., and finely ground. It is then dissolved at 20°—25° C. in nitric acid of 1.501 sp. gr., using 10 kilos. of acid to 1 kilo. of starch. The solution is added to a mixture of nitric and sulphuric acids, which, for the sake of cheapness, may be the waste acid from nitroglycerin manufacture, containing about 70 per cent. of sulphuric acid and about 10 per cent. of nitric acid. 5 kilos. of this waste acid are employed to every kilo. of the nitrated starch solution, the mixture being kept at a temperature of 20°—25° C. Nitrated starch is precipitated as a fine powder, and is collected on a filter of gun-cotton. The bulk of the acid is then removed from the precipitate by hydraulic pressure. The cakes produced are well washed in water, and treated with 5 per cent. of a soda solution. After 24 hours the cakes are ground between rollers, the creamy mass formed being afterwards dried by means of a centrifugal machine or a filter-press. Finally, about 1 per cent. of aniline is added to the residue (still containing 33 per cent. of water).

Nitrated starch so prepared dissolves readily in nitroglycerin. In the cold it forms at first a mass resembling lime, but as more of the nitrated starch is added a hard waxy material is produced. For details and drawings of apparatus, in which the above operations are to be performed, the original specification must be consulted.—H. T. P.

XXIII.—ANALYTICAL CHEMISTRY.

INORGANIC CHEMISTRY. QUANTITATIVE.

International Standards for the Analyses of Iron and Steel. Extracts from the work of the American Committee. J. W. Langley. Eng. and Mining J. 1890, 50, 455.

IN view of the work about to be commenced on the above subject by the committees in America, England, France, Germany, and Sweden, the American committee decided to make some preliminary trials of methods of analysis with a set of experimental standard steels before using the material of the international standards. The results were laid before the recent meeting of engineers, &c., in the United States. It appears from them that all analyses made hitherto of carbon by the combined double chloride and combustion process are unreliable on account of the variable action of the double chloride solution. The following are the analyses by C. B. Dudley of the same steel, wherein were used solutions of the uncrystallised and once and twice crystallised double chloride of copper and ammonium, these solutions also being used basic, neutral and acid:—

	Basic.	Neutral.	Acid.
Mother-liquor solution.....	1.078	..	1.142
First crystals	1.027	1.031	1.077
Second crystals	1.023	..	1.052

Other methods were employed without using the double chlorides, but the results varied from 0.788 to 1.040 per cent. The variable results obtained by various chemists of the committee are shown by the following few averages:—

By IGNEOUS COMBUSTION.

Chemist.	Ingot.	Hammered Bar.
Dudley	1.058	1.053
Blair, one method	1.014	1.022
Blair, another method ..	1.049	1.046
Blair, another method ..	1.010 to 1.044	..
Shimer	1.055	1.052

By CHROMIC ACID METHOD.

Langley	1.040 to 1.145	1.034 to 1.075
Langley, another set....	1.058	1.025

The conclusions arrived at by this preliminary investigation are:—(1.) That the combustion of carbon in a porcelain tube in a stream of purified oxygen, when the precautions indicated are used, gives reasonably accurate results. (2.) That the use of a small quantity of hydrochloric acid in a solution of the double chloride invariably gives higher results than when a neutral solution is employed. (3.) The most important discovery made by the committee in this work pertains to the variable action of the double chloride solutions.

The problems now before the committee, as suggested by these conclusions, are:—“The determination of carbon in steel by some direct process not involving the use of the double chloride; the direct combustion of finely divided metal in oxygen or chromic acid is one of these, or by fusion in a mixture of bisulphate and bichromate of potassium. The determination, if possible, whether a neutral or alkaline double chloride liquid may not dissolve a portion of the carbonaceous residuum, and thus lead to results which are too low. The determination whether the addition of acid simply prevents this tendency or whether the use of it favours the precipitation of pre-existing organic matter in the liquid, and its retention by the carbon sponge, thus leading to results which are too high. The investigation of the cause of the influence of repeated crystallisations of the double chloride on the apparent quantity of carbon.”—A. W.

The Analysis of Hypophosphorous, Phosphorous and Hypophosphoric Acids. L. Amat. *Compt. Rend.* **111**, 676—679.

THE oxygen compounds of phosphorus may be distinguished from each other by the quantity of oxygen they respectively need to convert them into phosphoric acid. This may be determined by oxidation with mercuric chloride or potassium permanganate. Rose applied the method of oxidation by mercuric chloride in the cases of hypophosphorous and phosphorous acids, but it has not yet been extended to that of hypophosphoric acid, as it was believed that this acid was unacted upon by mercuric chloride. Péan de Saint-Gilles (*Ann. Chem. Phys.* 1859, **55**, 374) experimented with hypophosphorous acid and potassium permanganate, and came to the conclusion that this acid was not completely oxidised to phosphoric acid by potassium permanganate, and that consequently this salt could not be used in estimating the acids of phosphorus. He further suggested the existence of a new body, P_3O_7 , since the oxidation appeared to stop at a point corresponding to such an oxide. Salzer, however, afterwards succeeded in oxidising hypophosphoric acid by potassium permanganate, and since this body does not exert so great a reducing action as

phosphorous and hypophosphorous acids, it seems all the more likely that these acids would be completely oxidised by potassium permanganate.

The author shows that hypophosphoric acid may be estimated by means of mercuric chloride, and that the volumetric estimation of phosphorous and hypophosphorous acids may be effected by means of potassium permanganate.

To effect the oxidation of hypophosphoric acid by mercuric chloride the operation must be carried out in a hot and acid solution. One gram. of the acid sodium hypophosphate, $P_3O_6Na_2H_2 + 6 H_2O$, was dissolved in 10 cc. of strong hydrochloric acid and nearly evaporated to dryness, the object of which was to bring about the decomposition of the hypophosphoric acid into phosphoric and phosphorous acids. The pasty mass was then dissolved in a little water, and a solution of mercuric chloride then added (68 grms. of mercuric chloride and 20—40 cc. of hydrochloric acid per litre; 1 cc. of this solution = 0.002 gram. of O). The liquid was then digested at 80° C. for 24 hours, the precipitated mercurous chloride collected on a filter, washed, dried at 100° and weighed. The filtered liquid must be tested to see if the reaction is completed. In using potassium permanganate for oxidising the acids of phosphorus, a solution of the salt equivalent to a solution of oxalic acid containing 63 grms. of the crystallised acid per litre was employed. The salt to be analysed was dissolved in about 20 cc. of water and 3 cc. of concentrated sulphuric acid. About 35 cc. of the permanganate solution were then added, and the solution heated to 50° C. and digested for half an hour. 20 cc. of oxalic acid solution were then added, which effected the reduction of the excess of permanganate, and the oxalic acid in excess was then titrated with standard permanganate solution.

Hypophosphites, phosphites, pyrophosphites, and hypophosphates may be estimated by this process. In the case of hypophosphates it is necessary to digest with the 20 cc. of water and 3 cc. of sulphuric acid for about half an hour before adding the permanganate. The author considers the mercuric chloride method the more accurate, and the permanganate method the more rapid.—H. S. P.

ORGANIC CHEMISTRY.—QUALITATIVE.

A Characteristic Reaction of Cocaine. F. de Silva. *Bull. Soc. Chim.* 1890, **4**, 471—473.

ALREADY appeared (*Compt. Rend.* **111**, 348—349), this *Journal*, 1890, 1155.

The Detection of the Impurities contained in Alcohol. E. Mohler. *Monit. Scient.* **34**, 893—898.

THE author has prepared separate solutions in pure alcohol (50 per cent. by volume) of all the impurities likely to occur in commercial alcohol, and has examined the action of the following reagents on these solutions:—1. Strong sulphuric acid. 2. Bisulphite of rosaniline. 3. Aniline acetate. 4. Potassium permanganate.

(1.) The colour produced by heating impure alcohol with strong sulphuric acid depends on the time and manner of heating, and it is therefore necessary to operate always under identical conditions. The following method of working was decided upon:—10 cc. of the alcohol to be tested (previously brought to a strength of 50 per cent. by volume) are placed in a flask of 125 cc. capacity and 10 cc. of sulphuric acid at 66° B. are gradually poured down the side of the flask so as to avoid mixing the two liquids. The flask is then held over a Bunsen flame and the contents are quickly mixed by shaking. The mixture becomes very hot, and after about five

seconds heating begins to boil. At this moment the flask is removed from the flame and allowed to cool in a place out of the reach of air currents. After cooling, the mixture is placed in a glass cell with parallel sides 25 mm. apart, and the colour is compared with Savalle's standard tints

(obtained by the action of sulphuric acid on alcohol, containing from $\frac{1}{10000}$ to $\frac{5}{10000}$ of a mixture of impurities). Operating in the above manner, the following results were obtained with solutions containing 1 in 1,000 of the various bodies.—

Alcohols.	Tint.	Aldehydes.	Tint.	Ethers.	Tint.
Capryl.....	7	Furfural.....	Intense black	Amyl acetate	3
Isobutyl.....	6	Isobutyric	9	Ethyl acetate	0
Heptyl	4	Paraldehyde	8	Ethyl propionate.....	0
Amyl.....	2	Propionic.....	7	Ethyl butyrate.....	0
Propyl.....	0	Oenanthylic	5	Ethyl isobutyrate.....	0
Isopropyl.....	0	Valerianic	5	Ethyl valerianate	0
Butyl, normal.....	0	Ethylic	3	Ethyl caproate	0
Glycerol	0	Methylal.....	2.5	Ethyl oenanthylate.....	0
Methyl	0	Acetal	1.5	Ethyl sebate.....	0
		Butyric.....	0	Ethyl succinate.....	0
				Ethyl benzoate.....	0
				Ethyl salicylate.....	0
				Methyl salicylate.....	0
				Methyl formate	0

The following table shows the smallest quantity of those substances, which give a colouration with sulphuric acid, that can be detected:—

Substance mixed with Alcohol of 50 Per Cent.	Dilution of the Solution.	Weight of Substance contained in 1 Litre of Alcohol.
		Grm.
Furfural.....	1 : 100,000	0.010
Paraldehyde.....	1 : 8,000	0.125
Isobutyric aldehyde	1 : 8,000	0.125
Ethylic aldehyde	1 : 8,000	0.125
Oenanthylic aldehyde	1 : 4,000	0.250
Propionic aldehyde	1 : 4,000	0.250
Valerianic aldehyde.....	1 : 4,000	0.250
Methylal.....	1 : 2,000	0.500
Acetal	1 : 2,000	0.500
Capryl alcohol	1 : 20,000	0.050
Isobutyl alcohol.....	1 : 8,000	0.125
Heptyl alcohol.....	1 : 2,000	0.500
Amyl alcohol	1 : 2,000	0.500
Amyl acetate	1 : 4,000	0.250

The colour produced is not proportionate to the amount of impurity present, as will be seen by reference to the next table:—

Substance Mixed with Alcohol at 50 Per Cent.	Savalle Degrees Corresponding to a Strength of		
	1 in 1,000.	1 in 2,000.	1 in 4,000.
Isobutyric aldehyde.....	9	3	$\frac{1}{4}$
Paraldehyde.....	8	4	$\frac{1}{2}$
Propionic aldehyde	7	2.5	$\frac{1}{4}$
Oenanthylic aldehyde.....	5	2.5	Trace of colour.
Valerianic aldehyde.....	5	1	Trace of colour.
Ethylic aldehyde	3	3	$\frac{1}{2}$
Methylal.....	2.5	Trace of colour.	..
Acetal	1.5	Trace of colour.	..
Capryl alcohol	7	3	$\frac{1}{2}$
Isobutyl alcohol.....	6	2.5	$\frac{1}{4}$
Heptyl alcohol	4	Trace of colour.	..
Amyl alcohol.....	2	Trace of colour.	..
Amyl acetate.....	3	Trace of colour.	..

(2.) The bisulphite of rosaniline solution was prepared as follows:—

	cc.
Solution of magenta (1 in 1,000).....	39
Sodium bisulphite at 34° B.....	20
Water	200
Sulphuric acid at 65° B.....	3

to be mixed in the order given.

10 cc. of alcohol to be tested are mixed with 4 cc. of the above reagent. The maximum violet colouration is developed in about half an hour, remaining constant for about 2 hours, when it begins to disappear.

The following table gives the smallest quantity of the aldehydes detectable in solution in 50 per cent. alcohol:—

Substance Dissolved in Alcohol of 50 Per Cent.	Strength of Solution.	Weight of Substance contained in 1 Litre of Alcohol.
Ethyllic aldehyde.....	1 : 100,000	Grm. 0·01
Acetal.....	1 : 100,000	0·01
Oenanthylic aldehyde....	1 : 100,000	0·01
Valerianic aldehyde.....	1 : 50,000	0·02
Propionic aldehyde.....	1 : 20,000	0·05
Isobutyric aldehyde.....	1 : 20,000	0·05
Paraldehyde.....	1 : 2,000	0·50
Methylal.....	1 : 2,000	0·50
Furfural.....	1 : 2,000	0·50
Butyric aldehyde.....	1 : 2,000	0·50
Acetone.....	1 : 2,000	0·50

(3.) Aniline acetate is peculiarly the test for furfural. It gives no colouration with solutions (1:1,000) of any of the other substances mentioned before. To apply the test, 10 drops of aniline and 2 cc. of acetic acid are added to 10 cc. of the alcohol under examination. The colour attains its maximum intensity in about half an hour, remains for some time and then disappears. A solution of furfural containing 1 in 1,000 gives a strong red colour. When only 1 in 1,000,000 is present the colour is distinct, and even when there is only 1 in 10,000,000 the tint is still perceptible. As the colouration obtained is proportionate to the amount of furfural present, that body may be estimated colorimetrically.

(4.) Potassium permanganate is instantaneously reduced by paraldehyde, isobutyric aldehyde, and isobutyl alcohol, in presence of acid.

25 cc. of solution of paraldehyde (1 in 1,000) absorbed 2·60 cc. of decinormal potassium permanganate. In the case of isobutyric aldehyde 0·7 cc. were required, whilst isobutyl alcohol absorbed 0·4 cc.

The other bodies before mentioned reduce potassium permanganate, but in such an irregular manner that it is impossible to distinguish between them.—H. T. P.

On the Estimation of Fat in Milk. J. Gorodetzky.

Zeits. f. angew. Chem. 1890, 118—121.

This paper contains a detailed description of extensive comparative experiments on the estimation of fat in milk by the "sand method," Rose's method, and Soxhlet's areometric method respectively. The general results show that:—Rose's method gives the most accurate results; in the "sand method" a more prolonged extraction must be used than usual, viz., 6 to 8 hours for ordinary milk and 10 to 20 hours for skimmed milk, and in order to make analyses by the "sand method" comparable, the duration of the extraction should be stated; the areometric method is simple and rapid but frequently gives too low results.

—H. K. T.

Contributions to the Chemistry of Fat. A. Thum. Zeits. f. angew. Chem. 1890, 482—483.

In these experiments it was sought to determine—(1) the behaviour on saponification with an insufficient amount of alkali, of a mixture of oleic, stearic, and palmitic acids; (2) in what proportion are the above acids liberated when oil containing them becomes rancid.

According to Baudot (D.R.P. 37,397) stearic acid can be prepared by treating the crude mixture of fatty acids with dilute potassium or sodium hydrate at a temperature of 65°—90°, the stearic acid combining with the alkali whilst the oleic acid rises to the surface. After repeated trials, however, the author failed to effect a separation by this means. In order to test the matter more thoroughly the following experiment was made.

Ten grms. of oleic acid having an iodine number = 78·7 were mixed with 10 grms. of commercial stearic acid. The mixture was dissolved in boiling alcohol, free from acid, and 48 cc. of potassium hydrate solution containing 1·73 gm. of solid potash were added, this amount of alkali being sufficient to neutralise the oleic acid only. The cooled liquid was mixed with a little water, shaken out with petroleum ether, and the petroleum extract washed with water and distilled. The residue, which weighed rather more than 10 grms., was boiled with dilute sulphuric acid, washed, and titrated by Hüll's method. It gave an iodine number = 37·2. The alcoholic soap solution left after the treatment with petroleum ether was next diluted with water, decomposed with dilute sulphuric acid, and the alcohol boiled off. The residue gave an iodine number 40·8. Hence there is no marked difference between oleic acid and solid fatty acids in their behaviour with alkali, and this reagent cannot be used for their separation.

In order to ascertain if oleic, palmitic, and stearic acids are liberated in the same or in a different proportion to that in which they exist in fats, when the latter become rancid, palm oil and olive oil were examined. These fats were mixed with alcohol and exactly neutralised at the boiling temperature with potassium hydrate, using phenolphthalein as an indicator. The neutral fat and soap were then separated from the mixture by means of petroleum ether as described above, the neutral fat being afterwards saponified. The original palm oil had an acid number 94·0, and an iodine number 55·0. The iodine number of the free acid was 52·1; that of the acid separated from the neutral fat was 55·2. Olive oil gave acid number 93·0, iodine number 79·2; the iodine numbers of the free fatty acid and of the fatty acid existing in the neutral fat being 77·8 and 79·0 respectively. These values show that the ratio between oleic acid and solid fatty acid in the free acids of palm and olive oils is the same as that in which they exist in the neutral fat.—H. K. T.

The Analysis of Dynamite. F. Scheiding. Zeits. f. angew. Chem. 1890, 614—615.

In the estimation of moisture in dynamite, the sample must be dried over sulphuric acid at the ordinary temperature, as nitroglycerin volatilises between 40° and 50° C. For the same reason when the nitroglycerin has been extracted with ether, after the latter has been evaporated, the residue must also be dried at the ordinary temperature in the same manner.

Should the dynamite be suspected to contain besides nitroglycerin another body soluble in ether, then the nitrate nitrogen and possibly the total nitrogen will require to be determined, the latter by Dumas' method. The former can

be estimated in a Lunge nitrometer, but the author prefers the Schulze-Tiemann process.

In the analysis of gelatin dynamite the first solvent to be used is ether; this destroys the gelatin, then the saltpetre is extracted with water, and after drying the residue, the collodion cotton is dissolved out by acetic ether. Should it be necessary to estimate the amount of gun-cotton present, then the acetic ether extraction must be preceded by treatment with "ether alcohol," as the acetic ether dissolves both nitrocelluloses.

The aqueous extract may also contain soda; it should therefore be made up to a known volume and in different portions should be determined: 1st, the total dry residue; 2nd, the alkalinity by titration; and 3rd, the nitrate nitrogen by Schulze-Tiemann's process. To collect the evolved nitrogen dioxide the author employs a burette of his own devising, described in this Journal, 1890, 896.

The presence of heavy spar in gelatin dynamite is to be regarded as adulteration, but in dynamite its presence is necessary when good kieselguhr is used in order to impart the required softness to the dynamite.—W. M.

ANALYTICAL AND SCIENTIFIC NOTES.

Dry Decomposition of Diazo-amido Compounds. F. Hensler. *Annalen*, 260, 227—250.

WHEN diazo-amidobenzene or its homologues is mixed with 8 to 10 parts of liquid paraffin, and the mixture heated, the diazo-compound first dissolves, and at a higher temperature is slowly decomposed with evolution of nitrogen, yielding ortho- and para-amidodiphenyl, diphenyl, benzene and aniline. Under the same conditions the diazo-compound obtained from para-toluidine yields toluene and para-toluidine, and that obtained from para-chloraniline gives chlorobenzene and para-chloraniline.

Benzenediazobenzylamide gives benzene, benzaldehyde, aniline, benzylaniline, and small quantities of diphenyl. Benzenediazopiperidide (565 grms.) yields benzene (122 grms.), diphenyl (23 grms.), piperidine, very small quantities of aniline, and a base which seems to have the composition C_8H_9N ; the author names this base *isopiperidine*, but it may be a mixture.

When benzenediazodimethylamide is dropped on to sand heated to 250° , it is decomposed, yielding benzene, diphenyl, dimethylamine, and small quantities of a liquid base, the nature of which has not been ascertained.—F. S. K.

The Injurious Action of Copper on Rubber. Engineer. 1891, 8.

DEWAR observed, accidentally, that metallic copper when heated to the temperature of boiling water in contact with the rubber exerted a destructive effect upon it. With a view of finding whether this was due to the copper *per se*, or to its power of conducting heat more rapidly to the rubber, he laid a sheet of rubber on a plate of glass and on it placed four clean discs—one of copper, one of platinum, one of zinc, and one of silver. After a few days in an incubator at 150° F., the rubber under the copper had become quite hard, that under the platinum had become slightly affected and hardened at different parts, while the rubber under the silver and under the zinc was quite sound and elastic. This would lead one to infer that the pure metallic copper had exerted a great oxidising effect on the rubber, the platinum had exerted a slight effect, while the zinc and silver respectively had had no injurious influence on it. A still more curious result was this, that the rubber thus hardened by the copper contained no appreciable trace of copper; the copper, therefore, presumably sets up the oxidising action in the rubber without itself permeating it.

Discovery of Hydronitric Acid (N_3H). D. Mendeleef. *J. Russ. Chem. Soc.* 22, 506—515.

THE author regards the discovery of this new compound by Curtius as one of the most brilliant acquisitions of chemical

science for the last year. It ought to throw considerable light on the whole field of little known metallic azo-compounds.

He considers hydronitric acid to be one of the nitriles of the ammonium salt of nitric acid.

Hydrates.	Ammonium Salts.	Nitriles.
Meta . . $N_2O_5 \cdot H_2O$	NH_4NO_3	$- 2 H_2O = N_2O$
Pyro . . $N_2O_5 \cdot 2 H_2O$	$NH_4NO_3 \cdot NH_3$	$- 3 H_2O = N_3H$
Ortho . $N_2O_5 \cdot 3 H_2O$	$NH_4NO_3 \cdot 2 NH_3$	$- 3 H_2O = N_4H_4$

the first nitrite being the common nitrogen monoxide, the second hydronitric acid, and the third an ammonium salt of the latter.

Being a nitrite, its H ought to have the properties of that of an acid and not of ammonia, like that of the hydrogen in hydrocyanic acid, the nitrite of formic acid. Partly by induction and partly by analogy to hydrocyanic acid, the author predicts for hydronitric acid, phenomena of polymerism, of complex and double compounds, and of isomerism. Thus he expects its ammonium salt (N_4H_4) to form an amide $N(NH_2)(NH_2)N$ as ammonium cyanate $CNO(NH_4)$ forms amide $(NH_2)CO(NH_2)$.

The double potassium feronitrates if existent ought to be characterised by their peculiar shades of colour; while the compounds corresponding to the Prussian blue ought to explode in the dry state.—N. W. T.

New Books.

AIDS IN PRACTICAL GEOLOGY. By GRENVILLE A. J. COLE, F.G.S., Professor of Geology in the Royal College of Science for Ireland. London: Chas. Griffin and Co., Exeter Street, Strand.

THIS work, which is inscribed in "Memory of many Expeditions," to Arthur Wells Bawtree, is a practical guide for the discrimination of minerals and rocks. The author boldly advocates a judicious union of chemical analysis with palaeontological research to this end, and on this principle his book is arranged. But in the scientific union referred to, the author is also by no means unmindful of the important aids afforded by spectroscopy and the microscopical examination of rock sections, which are included. Hence, to give the clearest idea of the scope of the book, and more especially to the practical man, it might be even better defined, as a work on practical mineralogy in which the aid of the science of palaeontology is in a due degree made use of.

In the compilation the author admits indebtedness to the instruction and published papers, of Judd, as also to the works of Brush, Laeroix, Rosenbusch, Zirkel, and others.

The work is profusely illustrated with 136 woodcuts, and closes with an instructive and practical "Suggested List of characteristic Invertebrate Fossils," and an Alphabetical Index to the entire volume.

The text is subdivided as follows:—Part I. The Sampling of the Earth's Crust. II. The Examination of Minerals. III. The Examination of Rocks. IV. The Examination of Fossils. The price of the book is 10s. 6d.

FUELS, SOLID, LIQUID, AND GASEOUS, THEIR ANALYSIS AND VALUATION. For the Use of Chemists and Engineers. By H. JOSHUA PHILLIPS, F.C.S. London: Crosby, Lockwood and Son, 7, Stationers' Hall Court, Ludgate Hill. 1891.

SMALL 8vo. volume, bound in cloth, price 3s. 6d. It contains Preface, Table of Contents, and Text covering 63 pages, containing also five wood engravings. The work treats of the following branches of the subject:—Methods of Analysis, Methods of Valuation, Tables, &c., and, finally, Analyses of

various Gaseous Fuels, such, *e.g.*, as American Natural Gas, Bessemer-Converter Gases, Blast-Furnace Gases, Blowhole Gases, Coal Gas, Gases occluded by Coal, Oil Gas, Siemens Producer-Gas, various Water-Gases. As stated in the Preface, "this little book comprises within small limits that which would otherwise have to be gleaned from widely-scattered sources and larger works, and the author's endeavour has been to make it a practical and theoretical help both to the chemist and the engineer."

TECHNISCH-CHEMISCHES JAHRBUCH, 1889—1890. Ein Bericht über die Fortschritte auf dem Gebiete der Chemischen Technologie, vom April 1888 bis April 1889. Herausgegeben von Dr. RUDOLF BIEDERMANN, 12^{ter} Jahrgang. Berlin: W. Carl Heymann's Verlag 1891.

OCTAVO volume, strongly bound in cloth and gilt-lettered, price 12s. The work contains Preface, Table of Contents, List of Abbreviated Titles of Works referred to in the text, 622 pages of subject-matter, including a copious Alphabetical Index of matter and authors. With the text are interspersed 300 wood engravings. A valuable review of New Books which have appeared during the session 1889—1890 is included—the subjects of such works covering the branches of Physics, Chemistry, Chemical Technology, Mineralogy, Geology and Botany.

The arrangement of the subject-matter is as follows:—I. Eisen. II. Alkali-metalle, Magnesium, Aluminium. III. Gold und Silber. IV. Kupfer. V. Blei. VI. Zink und Cadmium. VII. Zinn. VIII. Nickel und Cobalt. IX. Chrom und Mangan. X. Antimon, Arsen, Wolfram, Quecksilber, und Platin. XI. Chlor, Salzsäure. XII. Schwefel, Schweflige Säure, Schwefel Säure. XIII. Wasserstoff, Wasserstoff-superoxyd, Kohlensäure. XIV. Soda: 1. Kochsalz; 2. Sulfat und Soda. XV. Kaliumverbindungen. XVI. Ammoniak. XVII. Alkalische Erden. XVIII. Thonerde. XIX. Glas. XX. Thonwaren. XXI. Cement. XXII. Künstliche Steine. XXIII. Explosivstoffe. XXIV. Leuchtstoffe. XXV. Heizstoffe. XXVI. Zucker. XXVII. Stärke und Stärkezucker. XXVIII. Wein. XXIX. Bier. XXX. Spiritus. XXXI. Fette, Harze, Seife, &c. XXXII. Wasser. XXXIII. Nahrungsmittel. XXXIV. Düngemittel, Abfälle, Disinfection. XXXV. Gerberei. XXXVI. Leim. XXXVII. Organische Säuren. XXXVIII. Alkaloide. XXXIX. Farbstoffe. XL. Gespinnstfasern, Bleichen, Färben, Drucken. XLI. Papier. XLII. Photographie. XLIII. Apparate. XLIV. Bücherschau.

AN INTRODUCTION TO THE STUDY OF METALLURGY. By W. C. ROBERTS-AUSTEN, C.B., F.R.S., Chemist and Assayer to the Royal Mint, Professor of Metallurgy in the Royal College of Science, &c. London: Chas. Griffin and Co., Exeter Street, Strand. 1891.

OCTAVO volume, bound in cloth, price 7s. 6d. It contains front-piece illustrating a Stamp Battery and Frue-vanner, Preface, Table of Contents, and text covering 286 pages. The work is concluded with an Alphabetical Index. The pages of the book are illustrated by 83 wood engravings.

The subject-matter is sub-divided as follows:—Chap. I. The Relation of Metallurgy to Chemistry. II. Physical properties of Metals. III. Alloys. IV. The Thermal treatment of Metals. V. Fuel. VI. Materials and Products of Metallurgical Processes. VII. Furnaces. VIII. Means of supplying Air to Furnaces. IX. Typical Metallurgical Processes. X. Economic considerations.

The Chapters on "Alloys" and "The Thermal Treatment of Metals" offer special interest.

Trade Report.

TARIFF CHANGES AND CUSTOMS REGULATIONS.

CUSTOMS TARIFF OF NICARAGUA.

With reference to the statement published on pp. 640—51 of the *Board of Trade Journal* for December 1889, the following is a revised statement of the rates of import duty now levied under the Customs tariff of Nicaragua. This statement has been prepared by Mr. Marshall Vaughan, Her Majesty's Consul at Granada. The duty in each case is leviable per pound avoirdupois English weight, on the gross weight of the package, without any deduction whatever for cases or wrappers. When a package contains several distinct classes of goods the weight of the packing is distributed proportionately over each kind.

Note.—Peso = 2s. 10d. (about).

Articles.	Rates of Duty per English Pound.
MEDICINES, DRUGS, AND APOTHECARY'S SCANDRIES.	Pes. Cts.
Oils, olive, linseed, almond, castor, cocoanut, cod-liver, and any other similar oil	0'03
Acids, chlorhydric, muriatic, sulphuric, and nitric	0'03
Dol., carbolic, acetic, and oxalic	0'05
Spirits of turpentine, and gaseous, mineral, and acidulated waters	0'02
White lead or carbonate of lead	0'04
Alum	0'02

FRANCE.

Higher Duties on Chemicals.

The Tariff Commission has recommended that the duty on muriatic acid be raised from 30 to 37 cents. in the minimum list, and that a duty of 13 frs. and 9·50 frs., maximum and minimum respectively, be imposed on barium binoxide. Caustic soda is to pay 10 frs. and 8 frs. The duty in each case is the rate per 100 kilos.—*Chemist and Druggist*.

CANADA.

Fertilisers.

The law in Quebec as regards the importation, manufacture, and sale of fertilisers is very strict. Before any kind is offered for sale it must be approved of by the Government authorities, and the official analysis is kept for comparison with samples obtained any time within a year after the sale of the fertiliser has been authorised. In the case of fertilisers put up in packets, a copy of the Government

analyst's certificate must be printed on each packet. Then every manufacturer or importer who sells or offers fertilisers for sale must register his name and address every year with the nearest Inland Revenue officer, and pay a registration fee of one dollar.—*Ibid*.

MISCELLANEOUS TRADE NOTICES.

PAPERS INTERESTING TO TECHNOLOGISTS.

The following articles in the *Board of Trade Journal* for January 1891 will repay perusal:—

"Beer in the Philippine Islands," p. 56, *seq*.

"Flax Industry of New Zealand," p. 80, *seq*.

"Mine Explosions in France," p. 83, *seq*.

"India as a Wool-producing Country," p. 96, *seq*.

RUSSIAN PETROLEUM TRADE.

The following is extracted from a report by the Belgian Consul General at Odessa, dated the 12th December:—

In 1881 there were extracted 40,500,000 poods of raw naphtha (pood is equivalent to 36 lb. avoirdupois) from which 12,800,000 poods of petroleum were derived. Since then the produce of the mineral oil has gone on increasing, as is shown by the following figures:—

—	Naphtha.	Petroleum.
	Poods.	Poods.
1882	50,500,000	13,500,000
1883	60,400,000	15,100,000
1884	90,800,000	22,000,000
1885	117,100,000	30,000,000
1886	151,200,000	35,000,000
1887	166,000,000	44,300,000
1888	194,000,000	51,000,000
1889	205,500,000	61,200,000

The working of naphtha wells, in the island of Apcheron, occupies at the present time 60 companies or associations.

The first place belongs to Nobel Brothers, whose production, in 1889, was 31,800,000 poods. Then come: The Caspian Company, with 24,400,000 poods; Tsatouff and Co., 14,900,000; Tougieff, 14,000,000; Baku Naphtha Company, 13,200,000; Black Sea and Caspian Sea Company, 11,800,000 poods. These are the most important.

One hundred and sixty firms distilled naphtha in 1889. They produced 61,200,000 poods of petroleum and 3,400,000 poods of lubricants.

The export from Baku of naphtha and its derivatives is effected by the Caspian Sea chiefly towards Russia, and by the Transcaucasian and Black Sea Railway.

The exports *via* the Caspian Sea were respectively:—

In 1888, 20,000,000 poods of petroleum, 600,000 poods of oils, 53,600,000 poods of residues, and 6,100,000 poods of naphtha.

In 1889, 23,800,000 poods of petroleum, 300,000 poods of oils, 82,200,000 poods of residues, and 3,500,000 poods of naphtha.

Those by the Transcaucasian and Black Sea Railway were:—

In 1888, 30,000,000 poods of petroleum, 2,000,000 poods of oils, 5,500,000 poods of residues, and 700,000 poods of naphtha.

In 1889, 37,300,000 poods of petroleum, 3,000,000 poods of oils, 6,400,000 poods of residues, and 300,000 poods of naphtha.

Of the exports from Batoum, 4,400,000 poods were sent to Russia, 7,500,000 poods to Turkey, 7,100,000 poods to Great Britain, 6,600,000 poods to Austria-Hungary, 1,700,000 poods to Belgium, and 1,300,000 poods to France.

Towards the extreme East, Russia exported 3,100,000 cases in 1888 and 4,300,000 cases in 1889.

Notwithstanding the competition of Russian petroleum, American production has steadily gone on increasing. In 1888 the United States exported 130,000,000 poods; in 1889 they reached the figure of 155,000,000 poods.

NORWEGIAN INDUSTRIES.

Norway is wealthier in nickel ores than any other European country, but only two mines are now working, producing from 100 to 130 tons per annum. The price of the metal, which in 1875 was 20 kröners per kilogramme, has now fallen to 4 kroners per kilogramme.

Notwithstanding the depression in the wood-pulp business, new mills are still building in this country, and the exportation of pulp shows a steady increase. At present the Norwegian mills number 54, and the production will probably soon exceed the demand. The exportation of mechanical pulp rose in 1889 to 200,000 tons from 100,000 tons in 1885, while that of chemical pulp was estimated at 35,000 tons, against 24,000 tons in 1888. The prices of the latter article, which was produced at 15 mills, 11 of which were for sulphite pulp and four for sulphate cellulose, were considered remunerative, notwithstanding the increasing price of the raw materials. The aggregate value of pulp exported in 1889 was estimated at 3,210,000 dols. America is still a heavy importer of Norwegian pulp, chiefly shipped by the direct Thingvalia line to New York, although her own production of wood pulp has more than trebled during the last 10 years.* The exportation of pulp from this district to the ports of New York, Boston, and San Francisco amounted, according to the declared exports, in 1889, to 17,872 tons, most of which was chemical pulp, against 17,354 tons in 1888.—*Board of Trade Journal*.

OPIMUM CULTIVATION IN THE CHINESE PROVINCE OF SZ-CHUEN.

The following account of the cultivation of opium in the Chinese province of Sz-Chuen appears in the last report by the United States Minister at Pekin:—

The growth of opium has in recent years assumed great importance in Eastern Sz-Chuen. The poppy is grown over vast areas, forming, in many instances, a regular winter crop of the bean and Indian corn lands. This crop is very profitable to the farmer, not only for the drug produced from the sap, but for the oil pressed from the seed, the lye manufactured from the ashes of the stalks and the leaves, which furnish food for pigs. Thirty catties of seed will yield 10 catties of superior oil for illuminating purposes or for food. Though it is doubtless chiefly for the opium produced that it is cultivated, it is said that the other products of the poppy would remunerate the grower. It is not difficult to raise, will mature in time to allow other crops to ripen on the same ground the same year, and the opium produced is readily converted into cash, all of which tends to make it popular with the farmer. The facility with which opium, on account of its convenient form and small bulk in comparison with its value, can be carried over the mountainous roads of Sz-Chuen, enabling the bearer to evade vexatious *likin* stations and to smuggle it duty free into neighbouring markets, tends also to make it an exceedingly profitable product. Some idea of the inducement to the smuggling can be formed when it is remembered that the Customs duty on imported opium is 110 taels per chest. A large percentage of that produced in Sz-Chuen evades all taxation whatever. The area under cultivation annually increases, and the drug of Sz-Chuen, with that of Manchouria, to which, however, it is inferior, constantly encroaches on the market of the Indian product.

THE AMERICAN WOOD PULP TRADE.

Bradstreet's for the 29th November says:—

The American output of wood pulp has more than trebled within the past 10 years. It is now ardently expected by the manufacturers that they will not only be able to supply

the home demand, but that the exports will soon be as large as the imports of the last few years. The new inventions and processes which are constantly being constructed are rendering it possible to use it in making all grades and styles of paper, and it is now found also that by mixing chloride of zinc with the pulp a substance as tough as wood is produced, which has been made into gas pipes, boxes, and boards suitable for roofing.

The enlargement of old mills and the construction of new ones to meet the increased demand is not confined strictly to the east, but is progressing as rapidly in the south and west. While the production of straw fibre has increased 76 per cent. since 1880, the production of wood pulp has increased 500 per cent. The process of making pulp was patented in 1858, and up to 1881, when the patent ran out, its manufacture was controlled by five firms. There are now 210 factories engaged in its manufacture, 183 producing it by the mechanical process, 15 by the soda, and 12 by the sulphite methods. Of the mills employing the mechanical process, 62 are in New York State, of which the majority are located among the Adirondack mountains. In the last three years 200,000 acres of spruce and hard timber have been cleared to supply these mills. These factories have a daily capacity of 969,800 pounds, or about three times the output of the 18 mills in the State of Maine.

But the chemical processes, of which there are now two, are rapidly gaining favour over the older and slower mechanical method. The chemical pulp mills are mostly in the east, principally in Maine, Massachusetts, and New York. They differ only as to the method of reducing the thin pieces of wood to fine threads, or, as it is generally known, pulp. One method employs an acid, and the other an alkali, to disintegrate the fibres. After the wood has been reduced to pulp, the substances used in effecting this result are then eliminated by processes which save from 70 to 80 per cent. of the chemical solution, which can thus be used over and over again in further manufacture.

It is claimed, after many careful tests by distinguished German chemists, that paper produced by the *mitscherlich* or sulphite process exceeds all other papers in strength, surpassing paper made from rags by from 17 to 27 per cent. in tensile tearing strength, but falling below this paper in elasticity by 38 to 58 per cent.

The presence of resinous matter in the pulp diminishes by so much the elasticity of the fibres, and as the strength of the paper depends upon the degree of elasticity of the fibres, recent inventions have been directed to attaining this result. The fact that the quality of paper made from pulp in this country has been steadily improving within the past two years is sufficient evidence that the various processes are rapidly reaching perfection. It is also becoming possible to use a larger per cent. of pulp in the manufacture of paper. While a few years ago the common newspaper contained but from 50 to 75 per cent. of pulp now it contains over 90 per cent. This has enabled printers to run their presses at a high rate of speed, for the greater the per cent. of pulp the faster will it absorb the ink.

For the nine months ending September 30th, 1890, the imports of wood pulp amounted to 1,182,193 dols.; for the same period of the preceding year it was but 497,454 dols., or about two-fifths as large. The value of the wood pulp imported during the last three years about equalled the imports of paper.

MINING AND OTHER INDUSTRIES OF CHILI.

The following statistics of the mining industries of Chili are extracted from the last report of the Belgian Representative at Santiago:—

Different Mines.

The general exports of mineral products were less by 6,750,000 piastres in 1889 than in 1888; in fact this export represented, in 1888, 63,200,000 piastres, and in 1889, 56,450,000 only. The diminution is due to the low prices of copper and nitrates.

* See Report on American Wood Pulp Trade.

Copper.

From 1884 to 1888 Chili has exported about 1,402,000,000 kilos. of fine copper, worth about 467,500,000 piastres. Copper in bars was exported in 1888 to the value of about 14 millions; in 1889 hardly 6,000,000. During the first quarter of 1890 copper in bars to the value of 1,200,000 piastres only has been exported.

Iron and Coal.

The exports of manganese ores were valued in 1888 at 180,000 piastres; in 1889, 265,000 piastres; of mineral coal, in 1888, at 1,300,000 piastres, representing 128,000 tons; in 1889 they reached 146,000 tons, worth 1,315,000 piastres.

Saltpetre, Nitrates.

While, in 1889, the Customs revenue of Valparaiso, Talcahuano, Coquimbo, Coronel, Caldera, and Carrizal-Bayo fell off by reason of the diminution in the export of copper and wheat, that of Iquique, Pisagua, Antofagasta, Taltal, and Tocopilla increased by reason of the advance in the export of nitrates.

In 1888, 785,000,000 kilos. of nitrates were exported with a value of 34,000,000 piastres, and in 1889, 921,000,000 kilos., worth 36,000,000 piastres; in 1888, 91,000 kilos. of iodine, worth 900,000 piastres, and in 1889, 200,000 kilos., worth about 2,000,000 piastres.

In the first four months of 1890 the export of nitrates aggregated about 248,000,000 kilos., worth nearly 9,000,000 piastres, paying 3,000,000 duties, and more than 2,000,000 surtax; in May the export and sale were 1,990,500 kilos., worth from 2.47½ to 2.65 piastres per kilogramme. During the year 1889 the port of Iquique shipped 440,000,000 kilos. of nitrates.

THE MINERAL WEALTH OF CANADA.

The annual volume of statistics collected by the Geological Survey of Canada has, says the *Canadian Gazette*, just been issued at Ottawa. The mineral output of the country in the past year is valued at 3,909,000*l.*, showing an increase of 600,000*l.* for the twelve months. There was an increase of 60,000*l.* in the value of minerals exported, which reached a total of 883,834*l.* More than 80 per cent. of this, amounting to 750,670*l.*, went to the United States, while this country took minerals valued at 84,471*l.*, and 30,662*l.* worth went to Newfoundland. The mineral exports included (in value) gold, 121,850*l.*; asbestos, 72,000*l.*; iron and steel, 62,000*l.*; gypsum, 39,000*l.*; copper, 33,691*l.*; phosphates, 78,953*l.*; silver, 42,230*l.*; lime and cement, 32,251*l.*; petroleum, 2,151*l.*; mica, 6,100*l.*; iron ore, 7,973*l.*; manganese, 5,870*l.*; sand and gravels, 10,530*l.*; salt, 478*l.*; and slate, 660*l.*; with 9,915*l.* worth of wrought and unwrought stone, and 1,257*l.* worth of glass and glass ware.

Far the most important in the list of Canadian minerals, however, was coal, of which 2,719,478 tons were produced, and 665,315 tons were exported, the values being 1,116,836 and 466,981*l.* respectively. The coal production showed an increase of 61,344 tons and 65,000*l.*, but the average increase of the past few years was not maintained. The quantity produced by the Nova Scotian mines, indeed—1,967,032 tons—was less than the previous year's output by 22,000 tons; and the North-West Territories fell off to the extent of 17,760 tons, bringing their figure down to 97,364. On the other hand, British Columbia's 649,409 tons were over 100,000 tons more than in the previous year. No less than 1,600,021*l.* worth of coal was imported to the Dominion, anthracite contributing most largely to this amount.

The total value of minerals and mineral products imported by the Dominion during the year was 5,130,533*l.*, including iron and steel, 1,930,130*l.*; petroleum, 101,199*l.*; paints, 106,670*l.*; lead, 71,346*l.*; tin, 266,913*l.*; salt, 61,212*l.*; glass and glass ware, 251,532*l.*; brass and copper, 198,359*l.*; building stone, 41,221*l.*; precious stones, 31,989*l.*; marble, 21,819*l.*; zinc, 21,219*l.*; asphalt, 6,710*l.*

THE SUDBURY NICKEL DEPOSITS IN CANADA.

The *Canadian Gazette* says that the commissioners appointed by the United States naval authorities to visit and report upon the nickel-bearing districts of Canada have presented their report to the Washington authorities. It is dated October 14th, 1890, and is signed by Commodore William F. G. Folger, Chief of the Bureau of Ordnance, and Lieutenant B. H. Buckingham, an officer of the department, and furnishes a valuable confirmation of previous unofficial reports upon the wealth of nickel-bearing ores in the Sudbury district. These extracts from the report will indicate its general character:—

We are fully convinced, from the surface indications and the shafts already sunk, that they have an amount of mineral which cannot be exhausted by this generation. The deposits of nickel lie between walls of granite and diorite, and are easily to be distinguished, showing that there was absolutely no danger of the commissioners being deceived by mere surface indications.

But not only is the ore easily distinguished, it is easily handled when branch railways are built to the mines. The report states that the country for hundreds of miles is broken by rocky ridges from 100 to 600 feet high, with bare rocks cropping out in many places and the rest covered by a thin soil upon which are pine forests. "Between the hills are marshy valleys and numerous lakes and streams capable of furnishing abundant water-power." And again:—"It is important to notice, from an economic point of view, that these ores can be smelted in their natural state—that is, they do not require the admixture of fluxing substances. The dead pine timber found in great abundance in the neighbourhood, and which can be delivered at the furnace at 1 dol. 80 cents a cord, is a good fuel for roasting, though hardwood would be better, but owing to the fusible qualities of the ores and the intermixed rock, it answers the purpose. Coke is hence the only material that has to be brought from abroad. This is procured from Pittsburg, and can be delivered at the works at 7 dols. a ton."

The report closes with a summary in figures. The commissioners give an "estimate of tons of ore above the surface of the ground in deposits seen by us—650,000,000." That is, as the *Toronto Globe* puts it, an amount equal to five times all the iron that has been taken out of the rich mines of the Lake Superior district (United States side) in the whole 40 years of their working. If this ore were raised and shipped it would give more than three times as much freight as the whole of the railways of Canada have raised since the first locomotive began to run. The amount of ore taken from the mines up to October 1st is about 175,000 tons. The daily crushing capacity of the machinery at work on the ground is about 1,750 tons, and the daily furnace capacity of matter is about 100 tons.

MINERAL WEALTH OF NEW SOUTH WALES.

A volume, entitled "The Wealth and Progress of New South Wales, 1889—90" by Mr. T. A. Coghlan, Government Statistician, has recently been issued from the Government press at Sydney.

In that section of the book dealing with mines and minerals, the following table is published showing the approximate number of persons actually engaged in the principal departments of mining during each of the past seven years:—

Persons engaged Mining for	1883.	1884.	1885.	1886.	1887.	1888.	1889.
Gold.....	6,750	6,548	5,911	6,767	6,060	8,278	10,192
Silver and silver lead	..	45	929	1,297	1,670	4,215	6,587
Copper	1,913	1,746	1,000	622	503	1,214	542
Tin	4,100	2,850	3,395	2,814	3,188	3,439	1,234
Coal	5,481	6,227	7,097	7,847	7,998	9,301	10,277
Shale	293	116	324	100	120	253	158
Total....	18,537	17,532	18,656	19,447	19,539	26,760	28,970

There were also 47 men engaged in mining for bismuth, 90 iron miners at Lithgow, and 77 men mining for various other minerals, making a total of 29,184 miners at work in 1889, representing with their families a population of about 138,000 persons directly dependent upon mining for a livelihood.

The summary here under shows the quantity and value of the products of the various minerals since their first discovery, as well as the quantity won in the year 1889. It will be seen that the colony has produced various minerals of the total value of over 75½ millions sterling:—

Minerals.	During the Year 1889.		To the end of the Year 1889.

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND
MACHINERY.

APPLICATIONS.

1890.

20,445. E. A. Cowper. Improvements in the method and apparatus for drying air for metallurgical and other processes. December 15.

20,606. R. J. M. Regnault. Improvements in gas furnaces for use in glass and other works. Complete Specification. December 17.

20,834. F. C. Nunn. Improvements in apparatus for purifying water. December 20.

20,844. J. L. Wade. An improved indestructible compound for protecting boilers, pipes, cylinders, and other like bodies, and preventing radiation. December 20.

20,951. J. A. Drakenberg. A mode of and apparatus for separating fat, grease, or other impurities from the feed-water of steam boilers and other water. December 23.

20,955. O. Clausen. A manufacture of porous magnesian bricks for the linings of stoves, furnaces, fireplaces, and flues, and the construction of stoves and furnaces with such bricks. December 23.

1891.

84. C. G. Mayer. Improvements in or appertaining to refrigerating apparatus. Complete Specification. January 2.

101. W. H. Wilcox. Improved filter for oils, lubricants, and other fluids. January 2.

381. C. Herzog. An improved pump, specially applicable to thick or viscous fluids. January 8.

384. E. Crowe, R. Howson, and G. Dyson. Improvements in or relating to multiple-effect evaporating apparatus, applicable for the manufacture of salt from its solution, and the concentration or evaporation of other liquids. January 8.

COMPLETE SPECIFICATIONS ACCEPTED.*

1889.

20,792. A. Lussardi and A. Falco. Pressure and vacuum gauges. December 31.

1890.

1307. A. Capillary. Apparatus for filtering liquids. January 14.

2070. C. A. Sahlström and A. F. Hill. Furnaces for burning liquid fuel. January 14.

2218. R. Marshall and E. FitzGerald. Surface condensers. January 21.

2313. T. Wrigley. Mechanical stokers. January 21.

2427. A. Fryer. Process and apparatus for evaporating solutions or liquids. January 14.

2502. W. R. Renshaw. Apparatus for heating, cooling, and condensing fluids. January 21.

3186. J. Procter. Mechanical stokers. January 7.

4594. E. Jones. Apparatus for separating liquids or solids from vapours or gases in which they are suspended. January 21.

6460. J. von Langer and L. Cooper.—From G. Pietzka. Recuperators for utilising the waste heat of furnaces. January 21.

11,807. W. P. Thompson.—From A. Raps. Mercurial pumps. December 31.

16,761. W. P. Thompson.—From A. Mason and J. Wilson. Process and apparatus for effecting and maintaining combustion in secondary chambers of furnaces. January 14.

19,110. J. A. Morrell. Methods and apparatus for evaporating and concentrating solutions. January 21.

19,587. F. Soxhlet. Method of closing bottles suitable for sterilised liquids. January 7.

19,736. A. Hart. Vessels and appliances for boiling, infusing, steaming, washing, and bleaching. January 7.

20,606. R. J. M. Regnault. Improvements in gas furnaces for use in glass and other works. January 21.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

1890.

20,752. V. B. Lewes. Improvements in the manufacture of hydrogen gas, or a mixture of hydrogen and carbon monoxide, and apparatus therefor. December 19.

1891.

23. J. O. Spong. Improved arrangement of apparatus for obtaining chromatic illumination from gas or other flame. January 1.

112. H. Williams, of The Illuminating, Heating, and Power Gas Co., Limited. Improvements in exhausters and blowers for gas or air. January 3.

179. A. S. Davy. Improved method of and apparatus for treating smoke and gases from furnaces and other fires. January 5.

340. C. F. Claus. Improvements relating to the manufacture and carburetting of hydrogen, and to apparatus therefor. January 7.

578. N. Bourgoïn and H. Decoree. Improved apparatus for making gas. January 12.

660. J. H. W. Stringfellow. Improvements in the manufacture of artificial fuel. January 13.

764. D. Rylands and R. Potter. Improvements in flues or other similar means for conveying combustible gas from the producer to the point where such gas is consumed. January 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1889.

19,310. J. Watts. Firelighters. January 14.

1890.

2559. H. S. Maxim and G. S. Sedgewick. Carburetting or enriching coal and other gas, and apparatus therefor. December 31.

6463. E. Neave. Method and apparatus for obtaining oxygen from the air. January 14.

9394. J. C. Chaudler. Charging gas retorts, and apparatus therefor. January 7.

14,115. H. H. Lake.—From J. Lundström and Co. Manufacture of artificial fuel. January 14.

14,968. W. R. Lake.—From N. O. Goldsmith. Apparatus for withdrawing coke from ovens. December 24.

15,379. J. Platt. Apparatus for obtaining more perfect combustion of fuel in furnaces. January 21.

16,760. W. P. Thompson.—From A. Mason. Method and apparatus for burning coal and hydrocarbon fuel. January 7.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, ETC.

APPLICATIONS.

1891.

249. H. E. Rycroft and A. Mason. An improved process of and apparatus for distilling and refining petroleum and other hydrocarbons; applicable also for distilling and refining animal, vegetable, and fruit oils, saccharine juices, syrups, essential oils, and other substances. Complete Specification. January 6.

327. M. Bohm. Improvements in distilling crude petroleum, mineral oil, tar, and the like, and in apparatus therefor. Complete Specification. January 7.

844. F. Lennard. Improvements in and apparatus for distilling, more especially intended for distilling tar. January 16.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

1890.

20,563. B. Willecox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture of indigo carmine from glycoecoll and its homologues and analogues. December 17.

20,845. H. H. Lake.—From Wirth and Co., agents of Kalle and Co., Germany. Improvements in the manufacture of colouring matters. December 20.

20,889. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Production of azo colouring matters. December 22.

21,102. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Production of compounds of gallic acid with primary bases. December 27.

21,205. T. Peters. Processes for the manufacture of red colouring matters. Complete Specification. December 30.

21,284. J. R. Geigy. Manufacture of diethyldibenzyl-diamidodiphenylmethan-disulpho acid and violet dyestuffs therefrom. December 31.

1891.

16. J. Reakes. Improvements in water stains for colouring or staining various surfaces. January 1.

517. C. R. Bonne.—From H. Köhler, Germany. Improved method of combining acetic radicles with aromatic amine. January 10.

551. J. Dawson and R. Hirsch. A new process for the production of colouring matters belonging to the induline series. January 12.

583. J. C. L. Durand, D. E. Huguenin, and A. J. J. d'Andiran. Manufacture of new colouring matters. Filed January 12. Date applied for June 13, being date of application in France.

857. S. Pitt.—From L. Cassella and Co. Improvements in new colouring matters from triphenylmethane. January 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

1828. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co. Manufacture of azo colouring matters. December 24.

3098. H. H. Lake.—From A. Leonhardt and Co. Manufacture of colouring matters. December 31.

3397. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co. Manufacture of alpha-naphthol sulpho acids and dioxy-naphthalene sulpho acids, and dyestuffs therefrom. January 14.

3398. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co. Manufacture of mordant dyeing azo colouring matters of the triphenylmethane group. January 14.

5155. The Clayton Aniline Co., Lim., and J. Hall. Manufacture of colouring matters. January 7.

18,526. J. Inray.—From La Société L. D. Huguenin et Cie. Manufacture of colouring matters obtained by the action of amines of the fatty series upon galloxy-amine. December 24.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

1890.

20,514. G. Broadhead and J. Clegg. Improvements in the treatment of spent tan for the production of fibrous material therefrom. December 16.

20,806. J. Longmore and R. Williamson. Improvements in the treatment of rhea and similar inelastic fibres. December 20.

21,230. J. W. Barker. Improvements in woven fabrics. Complete Specification. December 30.

1891.

92. C. W. Kimmins and T. Craig. See Class XII.

207. J. Lussiez et Cie. An improved apparatus for winding and dyeing wool or other textile materials. Complete Specification. January 5.

COMPLETE SPECIFICATIONS ACCEPTED.

1889.

20,314. H. A. Lowe. Treating or finishing materials from cotton or similar fibres containing cellulose. December 24.

20,665. C. Baswitz. Treating textiles by ammoniacal oxide of copper to render them waterproof and non-combustible. December 24.

1890.

18,018. A. J. Boulton.—From G. Rudel. Treating vegetable materials to obtain textile fibres, and cellulose for use in the manufacture of paper. January 14.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

1890.

20,748. R. Holliday and Sons, Limited, and P. R. E. Seidler. Improvements in dyeing and printing with certain azo colouring matters. December 19.

21,062. C. E. Maistre and J. M. Compagne. Improvements in or connected with the dyeing of textile fabrics or materials with indigo, and in the manufacture of saponaceous matter employed therein; also applicable for other operations in which saponaceous material is required. December 24.

1891.

1. E. V. Goad and F. Redman. An appliance for use in dyeing, blueing, and starching clothes and the like. January 1.

86. C. S. Bedford. Improved process of dyeing or of fixing certain colouring matter on cotton and other kindred material. January 2.

207. J. Lussiez et Cie. See Class V.

478. H. A. Foster and J. Frost. Improvements in means and method of dyeing or colouring wool, silk, hair, fur, feathers, and other animal or vegetable fibres, or plain, cut pile, raised pile, or looped fabrics composed thereof. January 10.

595. W. L. Wise, from K. Schniter. A process of dyeing or treating fibres. January 12.

679. L. Kern. A method of preventing the escape of noxious gases in the processes of bleaching and otherwise treating textile materials. January 13.

COMPLETE SPECIFICATION ACCEPTED.

1890.

3009. S. D. Keene. Method and apparatus for bleaching, dyeing, &c. fibrous materials. December 31.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

1890.

20,775. J. Hawliczek. Improvements in and connected with the manufacture of bleaching powder. December 20.

21,071. A. Campbell, W. Boyd, and A. J. Kirkpatrick. Improvements in and connected with the treatment of crude bicarbonate of soda to obtain caustic soda, carbonic acid, and other products. December 27.

21,078. J. Leith. Improvements in the production of bicarbonate of soda and sulphuretted hydrogen, and in apparatus therefor. Complete Specification. December 27.

21,217. C. W. Heaton. Improvements in the treatment by the Claus process of gases containing sulphuretted hydrogen, and recovery of valuable products therefrom. December 30.

21,225. F. M. Lyte and O. J. Steinhart. Improvements in the production of chlorine and of strong hydrochloric acid. December 30.

1891.

266. J. Anderson and A. Brand. Improvements in the manufacture of alkalis and chlorine. January 6.

891. O. Inray.—From The Farbwerke Greisheim on Main, W. Noetzel and Co. Process for obtaining pure nitric acid direct in nitric acid reaction apparatus. January 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1889.

20,078. A. Martignier. Extracting tartrate of lime contained in lyes, &c., and transforming it into cream of tartar or tartaric acid. December 24.

1890.

393. R. C. Wilson. Method and apparatus for evaporation of brine and manufacture of salt therefrom. January 11.

1584. F. Ellershausen. Manufacture of soda and potash. January 7.

3391. O. E. Pold. Process and apparatus for manufacture of salt. January 21.

12,670. J. Simpson. Process and apparatus for treating minerals or slag containing phosphate of lime, for obtaining the latter in a concentrated form, with or without the production of alkali as a by-product. December 31.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

1890.

20,121. D. Rylands and B. Stoner. Improvements in the manufacture of glass taps and glass tees and other hollow glass ware. December 15.

20,606. R. J. M. Regnault. Improvements in gas furnaces for use in glass and other works. Complete Specification. December 17.

20,857. G. Swift. Improvements in tiles, faience ware, and other fictile ware required to be cemented to plane or other surfaces. December 22.

20,866. D. Rylands and A. Husselbee. Improvements in glass measures, glass reservoirs or fountains, and other hollow glass ware, and in the process of manufacturing the same. December 22.

20,955. O. Clausen. A manufacture of porous magnesians bricks for the linings of stoves, furnaces, fireplaces, and flues, and the construction of stoves and furnaces with such bricks. December 23.

21,072. E. Arthur. An improved glaze or enamel for tiles, bricks, and like articles. December 27.

21,181. W. W. Pilkington. Improvements in furnaces and appliances for melting, firing, settling, and casting plate glass. December 30.

21,212. J. B. Alzugaray. Improvements in the manufacture of refractory materials or articles. December 30.

1891.

118. F. T. Pover. Improvements in or relating to ovens for the firing of bricks, tiles, potters' goods, and the like. January 3.

374. H. J. Godfrey. Improvements in the manufacture of soup, dinner, dessert, and other plates. January 8.

903. M. Bauer. Improvements relating to the manufacture of glass bottles and similar vessels, and to apparatus therefor. January 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

352. E. Robson. Making porcelain tablets or letters. January 14.

927. W. W. Pilkington. Kilns and machinery for annealing rolled plate and plate glass. December 24.

3203. C. Leigh. Coating and tinting glass surfaces. January 14.

18,609. J. Bond. Apparatus for drying bricks, &c. December 24.

20,606. R. J. M. Regnault. See Class 1.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

1890.

20,164. T. Curran. Improvements in portable plaster slabs, methods of making the same, and moulds therefor. Complete Specification. December 16.

20,782. W. Briggs. An improved marine cement. December 20.

20,918. C. G. Wernaer and O. Wernaer. Method of manufacturing artificial granite and marble. December 23.

21,278. E. Nutzinger. Improvements in asphalt pavements and coverings. December 31.

1891.

291. T. Potter. The construction of fire-resisting concrete floors and ceilings combined. Complete Specification. January 7.

524. T. D. Hayton. Improved means and apparatus for preparing paving and like slabs. January 10.

907. J. Siedler, L. G. Hamilton, and E. W. Dow. Improvements in the process of calcining gypsum. January 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

2896. W. Joy. Process and apparatus for manufacturing cement. December 31.

3413. W. T. Sier. Hardening and preparing soft porous stone for enamelling, &c. December 24.

17,795. F. Oschwald. New or improved building material. January 14.

18,459. C. S. Haensler. Fire and weather-proof roofing. December 31.

18,468. F. Jurschina and R. Ritter von Gunesch. Manufacture of artificial stone, and building blocks, &c. thereof. December 31.

18,732. A. Cajot. Apparatus for enriching phosphate of lime and phosphated chalks for the preparation of cements, marls, and starches. December 24.

18,924. A. F. E. de St. Dalmaz. Improvements in paving blocks. December 31.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

1890.

18,869. A. Gutensohn. Improvements in apparatus for preparing metal plates and sheets for annealing, and for coating with tin or other metal. Originally included in No. 18,869, and therefore dated November 21.

20,415. H. R. Haigh. Improvements in the construction of furnaces for puddling or heating and other purposes. December 15.

20,419. J. McCracken. Improvements in making steel. December 15.

20,445. E. A. Cowper. See Class 1.

20,446. E. A. Cowper. Improvements in the method and apparatus for drying air for blast furnaces. December 15.

20,520. Williams, Foster, & Co., Limited, and S. W. Carlton. Improvements in apparatus suitable for the reduction of copper from its ores and other copper-bearing materials, such as regulus and mattes. December 16.

20,533. D. Brennan, jun. Improvements in apparatus for reducing ores. Complete Specification. December 16.

20,550. S. O. Cowper-Coles. Improvements relating to the coating or plating of metallic articles, and to apparatus therefor. December 16.

20,588. R. Martin and R. Evans. Improvements in means or apparatus employed in pressing or consolidating quantities of scrap metal. December 17.

20,609. A. Watt. Improvements relating to the extraction of zinc and lead from their ores. December 17.

20,666. H. Pritchard. Improvements in and connected with the manufacture or production of aluminium. December 18.

20,721. J. F. Hall. Improvements relating to the casting of ingots and other forms of metal. December 19.

20,768. G. J. Atkins and E. Applegarth. Improved means and apparatus for separating alkaline and earthy metals and other products from the salts of such metals, or from other substances containing them. December 19.

20,895. J. E. Bott. Improvements in the manufacture of armour plates and other similar articles. December 22.

20,911. S. Elliott. An improved method of condensing lead and other metallic fumes arising from furnaces. December 23.

20,951. O. Murray.—From J. A. F. Bang and M. C. A. Rutlin. A process for annealing iron plates, and removing oxide from their surface. December 23.

21,009. G. H. Smith and B. Cooper. An improved method of and means for casting white metal couplings and other similar white metal objects required to stand confined pressure. December 24.

21,025. L. Mond. New or improved manufacture of articles of nickel, and of nickel-plated goods. December 24.

21,129. F. C. W. Harnsen. A new method of untinning the waste of tin plates by heating it with the liquid nitrate of potash or soda. Complete Specification. December 27.

21,221. W. D. Bohm. Improvements in and apparatus for the separation of gold and silver from ores or materials containing them. December 30.

21,222. F. Siemens. Improvements in the reduction of iron ore. December 30.

21,231. E. A. Bath. Utilisation of refuse or scoria of copper smelting furnaces as a grinding or polishing agent or as a substitute for emery. December 30.

21,266. B. C. Sykes and G. Bluniers. Improvements in furnaces for heating steel wire in the process of hardening and tempering, and also for appliances for removing the oxide or bluing when formed. December 31.

1891.

37. J. B. Alzugaray. Improvements in fluxes for use in treating metals, ores, and the like. January 1.

165. A. Sailler. Improvements in the manufacture or production of metal plates hardened at one side. January 3.

205. C. Cochrane. An improvement in blast furnaces. January 5.

210. T. Langer. Improved fusible mass for case-hardening purposes. January 5.

213. D. Edwards. Improvements in apparatus used in the manufacture of tin,terne, and other coated metal plates. January 5.

214. D. Edwards. Improvements in apparatus used in the manufacture of tin,terne, and other coated metal plates. January 5.

215. D. Edwards. Improvements in apparatus used in the manufacture of tin,terne, and other coated metal plates. January 5.

251. W. R. Hunsdale. Process for forming ingots. Complete Specification. January 6.

275. H. Pike. Improvements in metallic alloys. January 6.

283. E. L. Mayer. Improvements in or connected with the extraction and recovery of gold. January 6.

500. R. Heathfield. Improvements in the process of coating metals. January 10.

516. A. Watt. Improvements in the treatment of copper ores. January 10.

557. A. E. Tucker and F. W. Harbord. Improvements in the removal of scale from iron or steel sheets, plates, or bars, and apparatus for the same. January 12.

652. O. B. Peck. An improved process for centrifugally treating particles of metallic or mineral-bearing substances of different degrees of specific gravity. Complete Specification. January 13.

673. O. B. Peck. Improvements in machinery for centrifugally treating particles of metallic or mineral-bearing substances of different degrees of specific gravity. Complete Specification. January 13.

674. O. B. Peck. Improvements in machinery for centrifugally treating particles of metallic or mineral-bearing substances of different degrees of specific gravity. Complete Specification. January 13.

795. J. E. Bott. Improvements in the manufacture of ferro-bronze and other alloys. January 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

1355. A. E. Haswell and A. G. Haswell. Coating iron, steel, nickel, tin, &c. to prevent corrosion. December 24.

1913. W. P. Thompson.—From E. Carez. Utilisation of scrap tin orterne plates, &c. January 21.

2002. G. Shenton.—From M. J. Berg. Production of aluminium. January 21.

3275. G. Simonin. Reduction of metallic ores. January 14.

3369. G. H. Cammell. Welding metals. January 7.

3532. W. Crookes. Amalgamating and extracting gold from refractory and other ores. January 14.

16,724. J. B. Renshaw. Manufacture of cast iron. January 21.

18,171. W. P. Thompson.—From M. F. Coomes and A. W. Hyde. Manufacture and tempering of steel. January 21.

18,601. L. L. Burdon. Compound gold wire. December 24.

18,915. W. P. Thompson.—From C. H. Lund. Manufacture of coated aluminium plates or surfaces, and application of same for coating or soldering to other metals. January 21.

19,163. H. W. Lash and J. Johnson. Reduction of ores. December 31.

19,179. J. C. Bayles. Joining iron or steel plates or sheets by welded joints. December 31.

XL.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY

APPLICATIONS.

1890.

20,510. W. P. Thompson.—From C. L. Coffin. Improvements in welding metals electrically. Complete Specification. December 16.

20,632. S. O. Cowper-Coles. Improvements relating to the manufacture and coating of metallic articles by electro-deposition, and to apparatus therefor. December 17.

20,712. E. Ortell. Improvements in and relating to electric batteries. December 18.

20,784. W. J. Eogledue. Improvements in metallic elements for galvanic batteries. December 20.

20,838. H. Birkbeck.—From O. Henriksen. A new or improved dry couple or element for electrical purposes. December 20.

20,986. H. H. Lake.—From H. Lemp, United States. Improvements in apparatus for electrically welding and otherwise working metals. Complete Specification. December 23.

21,031. P. J. Davies. Improvements in the production of lead plates for secondary batteries, and the connections, straps, or lugs to the same. December 24.

1891.

49. W. Wensky. Element and process for producing constant electric currents. Complete Specification. January 1.

223. W. H. Todd. Improvements in primary electrical batteries. January 6.

400. T. D. Bottom. Improvements in and relating to the desilverisation of lead, and simultaneous manufacture of white lead by electrolysis of argentiferous lead. Complete Specification. January 9.

593. T. Coad. Improvements in electric primary batteries. January 12.

667. W. P. Thompson.—From The Hess Electric Storage Battery Co., United States. Improvements in electrodes for voltaic accumulators. Complete Specification. January 13.

668. W. P. Thompson.—From The Hess Electric Storage Battery Co. Improvements in or appertaining to voltaic accumulators. Complete Specification. January 13.

743. W. O. Rooper. Improvements in the application of electricity for mining purposes. January 15.

884. C. Wells. Improved apparatus for the production of electricity. January 17.

887. The Electrical Inventions Co., Limited, and A. Andreoli. Improvements in or relating to the electrochemical extraction of gold, silver, and other precious metals from their ores. Complete Specification. January 17.

899. H. T. Eager and R. P. Milburn. Improvement in electric cells or batteries. January 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

1246. D. G. FitzGerald and A. C. Falconer. Electrolytic generation of chlorine and compounds of chlorine with earthy bases, more especially for bleaching purposes. December 31.

1306. C. Smith.—From W. L. F. Hellesen. Galvanic dry elements. January 14.

2091. W. P. Thompson.—From The Gibson Electric Co. Secondary batteries and plates or elements therefor. January 14.

2845. E. T. Mackrill. Secondary batteries. January 21.

7186. W. P. Thompson.—From C. L. Coffin. Process and apparatus for welding metals electrically. December 24.

13,557. T. S. E. Dixon. Secondary batteries. January 21.

16,064. J. K. Pumpelly and F. Butterworth. Electrical batteries. January 14.

16,346. S. C. C. Currie. Apparatus for use in the distribution of electricity by storage batteries. December 24.

18,491. R. Kennedy. Dynamo-electric machines. January 7.

18,625. H. H. Lake.—From H. Lemp. Apparatus for electric welding, forging, &c. December 24.

18,631. H. H. Lake.—From E. Thomson. Welding metals by electricity. December 24.

19,155. H. H. Lake.—From G. E. Hatch. Electrical storage batteries. January 21.

19,162. M. W. Dewey. Electric welding and metal working. December 31.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

1890.

21,112. H. Harford. An improved lubricant. December 27.

21,196. J. W. Evans. Improvements in the naphtha process of extracting oil. Complete Specification. December 30.

1891.

59. H. Wilkinson. Improvements in the purification of oils and fats. January 1.

92. C. W. Kimmis and T. Craig. Improvements in the separation or treatment of fatty or greasy matters from the wash-waters of wool-washing or scouring establishments. January 2.

101. W. H. Willecox. See Class I.

COMPLETE SPECIFICATION ACCEPTED.

1890.

983. H. Grimshaw. Soap and soap-powder for use with hard and sea waters. December 24.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

1890.

20,690. A. van Winkle and E. N. Todd. Improvements in protecting sheets of gelatin by pyroxiline or nitro-cellulose varnishes. Complete Specification. Filed December 18. Dated applied for, June 6, being date of application in United States.

20,966. G. Stevens. Improvements in anti-fouling or corrosive compositions or paints. December 23.

1891.

169. N. B. Dennys. Improvements in anti fouling paint for submerged surfaces of wood and metal. January 5.

681. W. Astrop and F. H. Parker. Improvements relating to the manufacture of carbonate of lead or white lead, and to apparatus therefor. January 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

985. H. Grimshaw. A new white pigment. December 24.

1821. C. B. Phillips and H. R. Lewis. Application of metallic copper to the hulls of vessels or to submerged structures, to prevent fouling thereof, and manufacture of compositions or pigments to be used for this purpose. January 21.

18,609. J. Bond. Transferred to Class VIII.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

1890.

20,514. G. Broadhead and J. Clegg. *See Class V.*

20,827. J. Pullman. An improved process for treating and colouring leather. December 20.

1891.

601. A. J. Boulton.—From M. M. Rotten, Germany. Improvements in the manufacture of a light coloured product containing albumen and globuline from blood. January 12.

COMPLETE SPECIFICATION ACCEPTED.

1890.

9042. O. Potelune, J. Rivet, L. Rivet, and L. Sautour. Apparatus for treating skins. January 14.

XV.—AGRICULTURE AND MANURES.

COMPLETE SPECIFICATIONS ACCEPTED.

1889.

20,076. H. Fewson. Method of nitrogenising substances in the manufacture of manures. December 24.

1890.

16,793. J. Patterson. Fertilising compounds. January 14.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

1890.

21,066. A. Boake and F. G. A. Roberts. An improvement in the manufacture of caramel. December 24.

21,101. F. W. Tompson. An improvement in the manufacture of invert sugars. December 27.

1891.

581. H. H. Leigh.—From W. V. Fry, Peru. Process for the defecation of sugar-cane juice. January 12.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

1890.

20,130. P. L. F. E. Vignier. Improvements applicable to the manufacture of pure grape spirit, and apparatus used for the same or other spirits, and also the ageing of the same. Complete Specification. December 15.

20,803. T. Fletcher. *See Class XVIII. A.*

20,909. G. Keng. A yeast tube for conveying yeast from beer in casks during course of fermentation. December 23.

20,985. H. H. Lake.—From H. Götter, United States. Improvements relating to the manufacture of fermented liquids, and to apparatus therefor. Complete Specification. December 23.

1891.

654. D. Quertain and H. Becker. Improvements in the process of and apparatus for brewing beer. Filed January 13. Date applied for June 14, 1890, being date of application in Belgium.

852. F. König. Process and apparatus for the manufacture of champagne and other beverages charged with carbonic acid. January 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

2990. H. S. G. Stephenson. Apparatus for generating and supplying carbonic acid gas to vessels containing fermented liquor. January 21.

14,118. G. Roskilly. Composition for refining and heading malt liquors. January 14.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

1890.

A.—Chemistry of Foods.

20,411. E. Sonstadt. Improvements in stoppering or closing vessels containing solid or liquid articles of food or other organic matters, in order to exclude micro-organisms, and in sterilising such matters conjointly with the stoppering. December 15.

20,593. The Denayer's Peptonoids and Extract of Meat Co., Limited.—From A. F. Denayer. An improved preparation of meat and method of making the same. December 17.

20,640. W. Badenberg. Improvements in sterilising milk and other substances. December 17.

20,678. A. Farr and A. Velluet. The effectual preservation of meat, poultry, game, fruits, vegetables, and all other perishable articles from putrefaction and decay without deterioration of flavour or quality. December 18.

20,803. T. Fletcher. Improvements in the preparation of diastase for use in the manufacture of bread and biscuits, and for other purposes. December 20.

20,946. L. Breglia and F. Breza. Improvements in the process of and in the apparatus for preserving articles of food. Complete Specification. December 23.

21,006. E. Sonstadt. Improvements in obtaining an extract of malt and hops, and in preparing a confection of the same. December 24.

21,019. E. Sonstadt. Improvements in making an extract of coffee and confection of the same, and in preserving liquid coffee extracts. December 24.

21,068. E. G. N. Salenius. Improvements relating to the manufacture of butter, and to churns or apparatus therefor. Complete Specification. December 24.

21,106. E. Sonstadt. Improvements in making an extract of tea and a confection of the same, and in preserving liquid tea extracts. December 27.

21,213. W. H. Lever, J. D. Lever, and E. G. Scott. New or improved process for recovering the mustard from mustard dress, or for obtaining the mustard with little or no waste from the seed. December 30.

1891.

625. G. W. Patterson. Preservation of food. January 13.

B.—Sanitary Chemistry.

1890.

20,996. F. P. Candy. Improvements in the method of, and in means for, treating sewage and impure waters. December 24.

1891.

44. H. Fewson. Improvements in the treatment of sewage and other foul matters. January 1.

502. J. E. Keirby. Improvements in apparatus for feeding or supplying precipitating, deodorising, or purifying materials or chemicals in the treatment of sewage or other foul liquids, and for other analogous purposes. January 10.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1890.

2742. J. G. Johnson.—From C. Risk. Process and apparatus for curing cocoa, &c. December 24.

4554. J. Shoveller. Cooked food for horses, cattle, &c. January 21.

8551. A. W. Stokes. Means of obtaining acidity or alkalinity in milk and other substances. January 14.

B.—Sanitary Chemistry.

1890.

1623. W. Warner. Apparatus for treating sewage. January 14.

C.—Disinfectants.

1890.

1017. W. Danmann. Rendering tar oils soluble in water, and production of disinfectants and other useful products therefrom. January 14.

3134. I. S. McDougall and J. T. McDougall. Compounds for washing or dipping sheep and other animals for extermination of parasites. December 31.

XIX.—PAPER, PASTEBOARD, ETC.

APPLICATIONS.

1891.

341. H. Moss. Improvements in manufacturing pasteboards and such like. January 8.

748. R. C. Menzies, and E. J. Bevan. Improvements in the manufacture of paper for cheques and like documents. January 15.

826. R. Brown and G. Mackay. Improvements in paper-making machines for making the surface of the paper equal on both sides. January 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

2832. E. Applegarth. Treatment of straw, esparto grass, &c., and compounds therefor. December 31.

17,012. G. L. Anders and C. H. Elliott. Use and application of xylonite, celluloid, and the like. January 21.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

1890.

21,006. E. Sonstadt. See Class XVIII. A.

21,019. E. Sonstadt. See Class XVIII. A.

21,044. A. Foelsing. Process for the preparation of hop extract. December 24.

21,106. E. Sonstadt. See Class XVIII. A.

21,294. W. W. Horn.—From F. de Mare, Comte N. Ney, M. Sannier, and G. Dambmann. An improved process for the production of camphor. December 31.

1891.

48. G. Link and R. Avenarius. Improvements in the manufacture of artificial perfumes. Complete Specification. January 1.

115. G. Link and R. Avenarius. Improvements in the manufacture of artificial perfumes. Complete Specification. January 3.

249. H. E. Rycroft and A. Mason. See Class III.

588. H. H. Lake.—From Ichthyogesellschaft Cordes, Hermann & Co., Germany. Improvements in coatings for therapeutical purposes. January 12.

853. A. J. Boulton.—From O. Schweissinger and L. Hoffmann, Germany. Improvements in the manufacture of extract of hops. Complete Specification. January 16.

XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

APPLICATIONS.

1890.

20,438. R. W. Thomas. Improvements in and relating to flash lights for photographic purposes. December 15.

20,501. S. H. Fry. Improved method of holding and exposing sensitive photographic surfaces. December 16.

21,059. G. F. Redfern.—From J. M. Jordan. Improvements in or connected with the production of photographic negatives. December 24.

1891.

880. W. Mathieu. A process of photography by which from a single negative, permanent prints are produced in the natural colours of all objects. January 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

15,091. A. McDonald. Preparation of chemicals adapted to the development of photographic plates. January 11.

19,658. A. J. Boulton.—From G. Eastman. Photographic films. January 7.

XXII.—EXPLOSIVES, MATCHES, ETC.

APPLICATIONS.

1890.

20,978. H. H. Lake.—From G. M. Mowbray, United States. Improvements relating to the manufacture of nitro-cellulose or pyroxylin. Complete Specification. December 21.

21,122. G. Quick. Improvements in the manufacture and form of perforated cake powder for ordnance, a part of which improvements is applicable in the manufacture of gunpowder generally. December 27.

1891.

298. F. J. Ryves. Improvements relating to the manufacture of explosives, and to apparatus therefor. January 7.

330. C. R. E. Bell. Improvements in the manufacture of matches. January 7.

336. J. A. Johnson.—From Zellstoff-fabrik Waldhof, Germany. The treatment of cellulose for the manufacture of cellulose nitrates or gun-cotton. January 7.

813. G. G. Andre and C. H. Curtis. Improvements in the manufacture of gunpowder, and in apparatus therefor. January 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

2769. H. A. Schlund. Percussion fuses. December 24.

3604. F. E. D. Acland. Time and percussion fuses. January 14.

18,319. J. S. Walter. Explosive compounds. December 24.

XXIII.—ANALYTICAL CHEMISTRY.

APPLICATION.

1891.

713. M. M. Hauly. An improved method of and instrument for testing milk. January 14.

.....

THE JOURNAL

OF THE

Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 2.—Vol. X.]

FEBRUARY 28, 1891.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2/6.]

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.

COUNCIL FOR YEAR ENDING JULY, 1891.

President: E. Rider Cook.

Vice-Presidents:

Sir Lowthian Bell, Bart., F.R.S.	Ludwig Mond.
R. Forbes Carpenter.	Dr. Hugo Müller, F.R.S.
Prof. James Dewar, F.R.S.	B. E. R. Newlands.
James Duncan.	Dr. W. H. Perkin, F.R.S.
David Howard.	Dr. Edw. Selunek, F.R.S.
S. H. Johnson.	J. C. Stevenson, M.P.

Ordinary Members of Council:

A. H. Allen.	Prof. R. Meldola, F.R.S.
L. Archbutt.	E. K. Muspratt.
S. B. Boulton.	T. L. Patterson.
Jno. Brock.	Jno. Pattinson.
Jno. Calderwood.	Jno. Spiller.
H. Grimshaw.	T. W. Stuart.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Dr. Ferdinand Hurter.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

Sir F. A. Abel, F.R.S.	Prof. A. K. Huntington.
A. H. Allen.	F. Hurter, Ph.D.
L. Archbutt.	Ivan Levinstein.
G. H. Bailey, D.Sc., Ph.D.	Prof. R. Meldola, F.R.S.
Joseph Bernays, M.I.C.E.	Ludwig Mond.
H. Brunner.	E. K. Muspratt.
Prof. Frank Clowes, D.Sc.	B. E. R. Newlands.
W. Y. Dent.	C. O'Sullivan, F.R.S.
Prof. Jas. Dewar, F.R.S.	John Pattinson.
John Heron.	W. H. Perkin, Ph.D., F.R.S.
D. B. Hewitt, M.D.	Sir H. E. Roscoe, M.P., F.R.S.
David Howard.	John Spiller.
Prof. J. J. Hummel.	A. Norman Tate.
	Thomas Tyrer.

Editor:

Watson Smith, University College, London, W.C.

Assisted by the following Staff of Abstractors:

S. B. Asher Aron. IV., IX., X.	J. Walter Leather, } XV.
H. Auer. VII.	Ph.D. }
T. L. Bailey, Ph.D. Gen.Chem.	F. H. Leeds. III., XXI.
G. H. Beckett. . V., VI., VII.	A. Liebmann, Ph.D. { IV., VI.,
D. Bendix. III.	XX. }

NOTICES.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPORTSWOOD, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January and May 1883, and January, February, and April 1886. Members possessing old copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Crosswell. The stock of all other numbers is at present sufficient for the Council's requirements.

LIST OF MEMBERS ELECTED, 23rd FEBRUARY, 1891.

Beach, Edw. J., 1183, Locust Street, Dubuque, Iowa, U.S.A., chemist and soap manufacturer.

Carulla, Federico M., 84, Argyll Terrace, Derby, director of gunpowder factory.

Clayton, Jno. W., Bentfield, Alma Road, Aigburth, Liverpool, pharmaceutical chemist.

Colin, Theodore F., P.O. Box 393, Pittsburgh, Pa., U.S.A., chemical engineer.

Croschaw, J. F., 11, Rose Street, Fountain Road, Hull, analytical chemist.

Dowland, W. H., 54, Gilcull Road, London, S.E., works manager.

Fawcett, Jas. H., c/o Bank of Australasia, 4, Threadneedle Street, E.C., metallurgist.

Fleming, R. G., 5, Cheapside, Tudhoe Grange, Spenny-moor, co. Durham, analytical chemist.

Forrester, A. M., Port Dundas Chemical Works, 20, Canal Bank, Glasgow, analytical chemist.

Hopburn, G. Grant, Chemie Schule, Mulhausen, Elsass, Germany, chemist.

Jackson, Fred., 10, Half Moon Street, Manchester, operative chemist.

McKewen, Atholl F., 43, Gilmore Road, Lewisham, S.E., analytical chemist.

Newsholme, G. T. W., 74, Market Place, Sheffield, pharmaceutical chemist.

Phibbs, L., 67, Wallace Street, Stirling, N.B., technical chemist.

Robertson, Robt., 156, Bath Street, Glasgow, analytical chemist.

Schlesinger, H. A., Glenhurst, Coventry Road, Ilford, Essex, drug merchant.

Scott, Andrew, 2, Tevot Terrace, Kelvin-side, Glasgow, analytical chemist.

Skurray, Thos., United Breweries, Abingdon, Berks, brewer.

Taylor, W. Ambrose, Royal Geological Society of Cornwall, Penzance, chemical apparatus maker.

Ward, Geo. J., The Aves, Beeston, Nottingham, civil engineer.

CHANGES OF ADDRESS.

Adam, A. Larnmouth, Journals to Kestating, Newton Street, Greenock, N.B.

Ashplant, W. G., c/o Park Villa; Palmer House, Torrington, North Devon.

Barrett, A. A., Journals to Lion Staff Chemical Co., Oldham Place, Liverpool.

Boyd, Pythagoras, Journals to 50, Marshall Street, North Adams, Mass., U.S.A.

Bramwell, F., c/o St. Helens; Ethersall, Huxton, near Liverpool.

Brown, E. J., c/o 419; Box 174, Johannesburg, S.A.R.

Carter, W. Chas., c/o University Street; 28, Eblana Street, The Plains, Belfast.

Couche, C. W., Journals to 132, Duke Street, Liverpool.

Crake, Wm., c/o Nottingham Street; Dresden Terrace, Bawtry Road, Attercliffe, Sheffield.

Froehling, Dr. H., c/o South 12th Street; 10, North 14th Street, Richmond, Va., U.S.A.

Harris, Sydney L., Journals to School of Science, Rossington Street, Leeds.

Heath, G. L., c/o Boston; Calumet and Hecla Smelting Co., S. Lake Linden, Mich., U.S.A.

Herriot, W. Scott, c/o Demerara; 39, Darnley Street, Pollokshields, Glasgow.

Hewitt, Dr. D. B., c/o Winnington House; Oakleigh, Northwich.

Hunt, Richard, Journals to 7, Marine Crescent, Waterloo, near Liverpool.

Kipping, Dr. F. S., Journals to 7, Milborne Grove, South Kensington, S.W.

Krohn, F. W. T., c/o Newark; 13, Belsize Square, South Hampstead, S.W.

Lacey, T. S., c/o Beckton; Gas Light and Coke Co. Lupus Street, Pimlico, S.W.

SESSION 1890-91.

March 2nd.—Mr. V. H. Veley. "The Chemical Changes between Nitric Acid and Metals."

March 16th.—

Mr. W. Crowder. "Observations made in the Working of Vitriol Chambers."

Mr. A. H. Allen. "The Chemistry of Whisky and Allied Products."

April 6th :—

Election of five members to replace an equal number retiring from Committee. Nominations to be sent to the Hon. Secretary on or before Monday, March 24th.

Professor Vivian B. Lewes :—

1. "The Analysis of Illuminating Gases."
2. "The Products of Checked Combustion."

April 20th.—Mr. W. P. Rix. "Stoneware; and its Application to Chemical Apparatus."

May 4th.—Professor Dewar, F.R.S., and Mr. Boyerton Redwood, F.R.S.E. "A Process for the Conversion of Heavy Mineral Oils into Lighter Hydrocarbons suitable for Illuminating and other purposes."

June 1st.—Dr. W. S. Squire. "The Artificial Production of Cold theoretically and practically explained."

Meeting held Monday, January 19th, 1891.

MR. THOS. TYRER IN THE CHAIR.

At the commencement of the proceedings, the Chairman made a few remarks referring to the fact that the last issue of the Society's Journal had appeared somewhat later than usual. This, he said, was due to the fact that, for the first time in the history of the Society, the index for the year was included in the December number. He trusted that the modifications which had been introduced into it would render the new index of greater value to technologists and the members generally.

ON THE CONSTITUTION OF BUTTER.

BY J. ALFRED WANKLYN, CORRESPONDING MEMBER OF THE ROYAL BAVARIAN ACADEMY OF SCIENCES.

THE commonly received view of the constitution of butter is that it, like other animal fats, consists mainly of oleine and margarine, or rather of oleine, palmitine, and stearin; and that it differs from the common fats inasmuch as it contains a small proportion of butyrine and other glycerides. Twenty years ago I was of that opinion, and you will find that statement in my book on milk analysis. But since that time I have learnt better; and I will now describe some experiments made in 1883, but never yet published.

I took 50 grms. of butter with 9.42 grms. of dry hydrate of lime, making a total of 59.42 grms. These materials were placed in a platinum dish provided with a stirrer, and the vessel with its contents was heated on the water-bath and constantly stirred for a long period. From time to time it was allowed to cool, and was then weighed, five times in all. There was a steady loss of weight, and ultimately the weight of the compound fell to 58.510 grms., showing a loss of 0.910 grm. of water.

I attach great importance to this experiment. If butter were pure glyceride there could have been no such loss, inasmuch as hydrate of lime loses nothing in the water-bath, and hydrate of lime and a glyceride react without production of water, yielding only lime salts and glycerin. The loss of water could arise from two sources: either from the action of free fatty acid in the butter, or from the action of the lime on an iso-glyceride. An iso-glyceride, as I explained many years ago, is an ether of a glycerin in which all the hydroxide is allied with one atom of carbon. On saponification such an iso-glyceride yields an iso-glycerin which instantly falls to pieces and forms water and a fatty acid, which latter also gives water by reaction with lime. There are these two ways in which the water could be formed, and possibly there is a third.

Continuing the experiment on the saponification of butter, it was shown in a decisive manner that the yield of glycerin by butter is too small to admit of the possibility of butter being pure glyceride. The lime compound in the platinum dish weighed, as I have said, 58.510 grms. To it were added 6.460 grms. more hydrate of lime, making the total 64.970 grms. The mixture was then digested with 600 cc. of water and filtered, and the lime compounds were digested with 300 cc. of strong alcohol, the solution evaporated to dryness, and the residue weighed. The results were, in the case of the residue of the aqueous solution, 1.991 grms., and in the case of the alcoholic solution, 4.606 grms. The insoluble substance after thorough drying weighed 58.140 grms.

The work was done with great care; and there is a most satisfactory agreement between the weight of the total mass and the sum of the extracts and the insoluble residue. Thus :—

	Grms.
Aqueous residue.....	1.991
Alcoholic residue	4.606
Insoluble lime salts.....	58.140
	<hr/> 64.737

The material that produced these.. 64.970

The agreement, therefore, is very close. Considering the possibilities of error which must necessarily exist in such a determination, it is as close as we can expect to get. The difference is 2 decigrammes, and is due to the escape of butyric acid in the shape of butyric ether. I insist on the significance of the correspondence. It shows that nothing important had escaped by evaporation, or was otherwise lost. That the saponification was pushed to completeness was shown by the fact that the 600 cc. of water was not alkaline. That shows that the whole of the hydrate of lime was used up, and that perfect action must have taken place; and for every equivalent of butter acids there were two equivalents of lime. All the glycerin arising from the saponification of the 50 grms. of butter fat must have been comprised in the aqueous extract and in the soluble part of the alcoholic extract. These were 1.991 and 4.605 respectively, or 3.396 in all. From this a deduction of about 3 decigrammes has to be made for the lime in the extracts, which was determined in each case by actual experiment. This leaves approximately 3.1 grms. as the total amount of glycerin to be got from 50 grms. of butter, or 6.2 from 100 grms.

I believe that some chemists are under the impression that if you boil down a weak solution of glycerin it escapes with the water. The following experiment may be cited. Taking half a litre of water, I dissolved in it from 1 to 2 grms. of glycerin, and distilled off 250 cc. and examined the distillate. The total amount of glycerin in the distillates

did not exceed 2 mgrms. So the proof is double that there is no loss of glycerin. I have weighed all my materials, accounting for everything and experimenting directly; and the total amount of glycerin from 50 grms. of butter fat is not more than 3.1 grms.

If butter were a pure glyceride, it would furnish more than 10 grms. of glycerin from 100 grms. of butter fat, so that 40 per cent. of the glycerin is missing. That means that in every 100 parts of butter fat at least 40 per cent. is something else.

This result is diametrically opposed to the views that are held at the present day, but it is perfectly in harmony with the classical researches of Chevreul published early in the century. If you will consult that admirable book, Gerhardt's "Traité de Chimie Organique," published about 30 years ago, you will find an excellent résumé of Chevreul's researches, and in Vol. 2, page 855, you may read that when Chevreul examined a pure glyceride derived from beef fat he found 9.8 of glycerin, but when he used what he calls the stearin derived from butter, all he got was 7.2. I got 6.2 from the total butter. Chevreul got 7.2 from the less fusible portion of the butter. The stearin of butter is described as being obtained by partially melting butter, and taking out by pressure such part as will flow, leaving behind that which will not flow.

The nature of the butter acids has also been made the subject of study. The acids insoluble in water are commonly described as oleic, palmitic, and stearic acids. There is, however, no oleic, no palmitic, and no stearic acid, but something quite different. More than half of the fatty acid produced from butter fat by saponification is a new fatty acid of the formula $C_{31}H_{60}O_2$. This fatty acid, which I name alde-palmitic acid, bears the same relation to palmitic acid that aldehyde bears to alcohol. It melts at about 12° lower than palmitic acid, namely, at about 50° C. It is insoluble in water, sparingly soluble in cold alcohol, but at temperatures above 25° C. it is soluble in its own weight of alcohol. It is only moderately soluble in cold ether, but extremely soluble in boiling ether. Bisulphide of carbon and pentane dissolve it readily. It is a non-crystalline solid, with a lustre like silk. Its behaviour with alcohol is most extraordinary. I have here a specimen of the product prepared eight of nine years ago, and this little preparation was made this day by taking 1 part by weight of the acid and 5 parts by weight of alcohol, warming very gently until the acid dissolved, and then allowing to cool. The acid has the remarkable property of being able to solidify five times its own weight of alcohol. The bottle contains $1\frac{1}{2}$ grms. of the acid with 10 cc. of 85 per cent. alcohol, and, as you see, its contents do not flow.

When the contents are placed on filter-paper a change takes place. A part of the alcohol passes into the filter-paper, and there remains behind a chemical compound of the acid with alcohol, containing 1 molecule of the acid to 4 of alcohol. On heating in the water-bath more alcohol is lost, and there remains a compound of 2 molecules of the acid with 1 of alcohol.

This compound will just bear fusion in the water-bath, but if maintained there the alcohol goes off and the pure acid remains behind. I have a satisfactory analysis of the compound of 2 molecules of the acid with 1 molecule of alcohol. This analysis shows 11.65 per cent. of hydrogen. Palmitic acid contains 12.5 of hydrogen, and if the palmitic acid were combined with alcohol the percentage of hydrogen in the compound would be a little higher. A baryta salt was obtained by dissolving the substance in ether, and pouring the solution into baryta water, using a slight excess. On boiling, the baryta salt was precipitated to the bottom. The liquid was then decanted, and the almost dry precipitate washed with boiling water, dried in the water-bath, and then treated with cold ether. After removing the ether, the substance was again dried in the water-bath and analysed. The determination of barium was not by precipitation, but by ignition with sulphuric acid, which is a better process in such cases, and I obtained the theoretical quantity of baryta for the new acid. Palmitate of baryta contains 21.17 of barium. My salt contained 21.32, which is the theoretical number for alde-palmitate of baryta. The experimental

difference between these two formulae was 5 milligrammes of sulphate of baryta, and that is a quantity within the reach of the careful operator.

A silver salt has likewise been prepared. The baryta salt differs from the palmitate of baryta physically. The text-books describe palmitate of baryta as a lustrous crystalline compound. But the alde-palmitate is perfectly amorphous; it has no lustre whatever.

I have prepared a soda salt by taking alde-palmitic acid, carbonate of soda, and alcohol, and treating them in the water-bath. The soda salt contains two atoms of water of so-called crystallisation.

The various salts of the new acid are at present under investigation, and, as far as possible, I am avoiding preparation by double decomposition. I learnt this lesson more than 30 years ago from Bunsen, whose pupil I was. I had propionic acid, arising from a new reaction, and was about to make the baryta salt by double decomposition, when Bunsen said: "You must not make it in that way. You will risk getting a double salt, and I don't know what besides." So I set to work in another way, and got a baryta salt which gave me the theoretical numbers.

In operating upon butter for the extraction and separation of the butter acids, I base my process of separation on the observation that, whilst alde-palmitic acid is only sparingly soluble in cold alcohol—viz., to the extent of about 5 per cent.—the acids which accompany it are very soluble in cold alcohol. In one experiment, I operated upon 76 grms. of the insoluble fatty acids obtained by decomposing butter by means of potash and alcohol, with subsequent decomposition of the butter-soap by sulphuric acid. Starting with 76 grms. of the fatty acid, I mixed with it 25 cc. of alcohol of about 85 per cent. strength. The semi-solid mass was placed on bibulous paper, and pressed. The residue which the paper did not absorb was again mixed with 25 cc. of alcohol, and again pressed. After four such pressings (the body having thus been subjected to the solvent action of 100 cc. of alcohol), the final residue was put into a platinum dish, fused in the water-bath, and weighed. Its weight was 41.7 grms., and on being submitted to analysis, gave the following figures:—

0.2515 grm. substance taken: 0.264 grm. H_2O : 0.678 grm. CO_2 .

	Calculated.		Found.
C_{31}	408	73.65	73.50
H_{60}	66	11.91	11.65
O_2	80
	554	100.00	..

By using alcohol and bibulous paper, the 76 grms. was divided into two parts, viz., 41.7 grms. unabsorbed and about 34 grms. absorbed by the paper. By means of ether, 23 grms. of fatty acid was extracted from the first bundle of paper. The other bundles were not operated upon, as the more soluble part would not predominate. Instead of alcohol, ether may be used, and in a similar manner, only the quantity of ether must be much smaller than the quantity of alcohol employed in the operation I have just described. Operating on a sample of butter acids with ether, I have divided them into fractions, much in the same manner as when using alcohol.

The portion unabsorbed by the bibulous paper is alde-palmitic acid. What, then, is the portion absorbable by the paper? I have only partially investigated it at present; but this is certain: it is not oleic acid. It solidifies at about 30° C. I am at present at work on this body.

I must express my sense of the incompleteness of this investigation. The results have, however, been accumulating for nearly 10 years. The subject is one of extreme difficulty, and my opportunities of working at it have been very much restricted. I hope shortly to publish a more detailed account of alde-palmitic acid.

The specimen in this bottle is the remains of the 41.7 grms. of alde-palmitic acid prepared in 1882. When first prepared, it consisted of 1 molecule of alcohol to 2 of the acid, and on examination was found to lose quite enough on heating in the bath. After the lapse of eight years, however, it has lost the greater part of the alcohol, and diminishes in the water-bath only to the extent of 2 per cent. Traces, as evidenced by the smell, have in the course of years suffered etherification.

The small bottle which I passed round before contains the white jelly-like mass produced by bringing together the acid and a considerable quantity of alcohol.

Founded on the results of this investigation, there are practical methods of distinguishing between butter and butter substitutes, and these methods I have resorted to in dealing with the question of adulteration. At present, as is well known, though we can say whether a specimen of butter consists to a large extent (say half and half) of common animal fat, yet small quantities of adulterants are not ascertainable by the ordinary processes of examination. By new methods, there is a prospect of detecting the presence of about 2 per cent. of ordinary fat in butter.

DISCUSSION.

Dr. C. R. ALDER WRIGHT said that anyone who had attempted to follow the work done by the author in former years must feel that he had a difficult task if he endeavoured to controvert or even criticise his statements. He therefore felt some diffidence in asking one or two questions, though he did so purely for his own information. In the first place, he had gathered that the butter fat examined was not derived from any one particular kind of cow, and that there was a possibility that different species of the bovine race might yield different fatty acids. There was nothing to show whether the butter treated by the author was an abnormal specimen or of the usual average quality. In the next place, he had noted that the method adopted was carried out on quantities of material not exceeding 100 grms. in any one case. He would like to ask, therefore, whether the stearo-palmitine of the fatty acids was subjected to any treatment which would prove whether it was a homogeneous body or a mixture. If one started with one or two kilogrammes and fractionally crystallised or precipitated it, repeating the process fifty or a hundred times, one might get two fractions, one at one end of the series and another at the other end, which would present considerable differences. Such an experience was common in the history of fatty acids. He would like to know whether Mr. Wanklyn had satisfied himself that his alde-palmitic acid was one single substance and not a mixture, and if so, upon what evidence. With reference to the analytical figures, the difference between 21.17 and 21.32 was not so great as to lie outside the limits of experimental error, and the same remark would apply to the percentages of carbon and hydrogen determined by combustion. It hardly seemed to him to be legitimate to lay much stress upon a divergence of one or two tenths per cent. between the calculated and the found proportions as proving anything. The author had said that the body which he had named alde-palmitic acid bore the same relation to palmitic acid that aldehyde bore to alcohol. Was he to understand that it contained the aldehyde group COH? If so, he failed to see that it was a fatty acid at all, because as only two atoms of oxygen were present, it could not also contain the group CO.OH. If the author meant that it was a true fatty acid containing two atoms of hydrogen less than palmitic acid, then it was an unsaturated acid, and ought to combine with iodine or bromine. He would like to ask whether the iodine absorption had been determined. With regard to the percentage of glycerin, all would agree that the exact determination of that body was a very difficult point. Certainly some fatty matters either naturally contained or yielded larger proportions than others. In the case of cocoa-nut oil, for example, the quantity of glycerin obtainable generally fell but little short of the theoretical amount, calculated as a triglyceride, and assuming the mixture of fatty acids there present to have the molecular weight which represented their average, something like 200. But in the case of other substances, tallow, &c., it was often

difficult, even with the best processes, to work out such a quantity of glycerin as came up to 95 per cent. of the theoretical quantity, an amount easily obtainable in the case of cocoa-nut butter. With regard to the moist process of combustion, he did not know whether Mr. Wanklyn's patent for it had yet run out. The fact of its being a patented process had been in the way of his having any experience of it, and he believed that this was the case with most other chemists. With reference to the baryta salts, there was one method of preparing them which he had found convenient. It was a slight modification of the method recommended by the author, and consisted in treating with a small excess of hydrate of barium, blowing carbonic acid through the liquid, and subsequently boiling to decompose the bicarbonate formed. That method of working ensured that the whole of the acid was converted into the barium salt, whereas if the carbonate were used one could not always be sure what one would get. The molecular compound with alcohol seemed to be an interesting body; but he would point out that that was not the only case in which alcohol acted so remarkably. Even with calcium chloride and other inorganic salts, alcohol was known to combine and form crystallisable bodies, in the same way as water with sulphate of copper. As somewhere about two molecules of the new body were said to combine with one of alcohol, he would ask the author whether that did not rather suggest that he was dealing with a mixture of bodies, of which about one half combined with a molecule of alcohol, and the others did not combine at all.

Mr. OTTO HEHNER said that he would have personally preferred to have refrained from making any remarks, but he felt it to be his duty as a public analyst to make a few observations in reference to the paper on the constitution of butter. For a number of years past Mr. Wanklyn had given utterance to his views on that subject, but those views had not agreed with each other. He remembered that, as long ago as 1874, when it was first found that butter contained a larger quantity of soluble and a lesser quantity of insoluble fatty acids than had formerly been believed, Mr. Wanklyn pointed out that that difference was perhaps due to the butter fats analysed not being quite dry. That was the only way in which he could account for the deficiency in insoluble fatty acids. Later on, he started—though without giving any analyses—his iso-glycerin theory, which attempted to explain—and did, on paper, satisfactorily explain—the author's inability to get out of butter any glycerin. When it was shown afterwards that there was no difficulty in getting the theoretical quantity of glycerin, they heard no more of the iso-glycerin theory until to-night. With regard to the matter before the meeting, he must confess that he had never known such great and startling deductions drawn from such small analytical results, especially by a man with a European reputation. What was the experiment which the author had first described, and upon which the theories propounded were based? He added some lime to a certain quantity of butter fat and heated the mixture. There was a loss. That loss was assumed to be due to water. He (Mr. Hehner) would like to see some evidence of that. It was well known that if lime were added to fat, a more or less incomplete saponification ensued; glycerin was formed; and glycerin was a somewhat volatile body, as anybody might easily convince himself by placing some concentrated glycerin in a water oven, when thick white vapours would be seen escaping. It was only a very small loss; but Mr. Wanklyn proceeded to account for it by the assumption that butter was not an ordinary glyceride. Mr. Wanklyn had then tried to estimate the glycerin. But he surely knew that a fat could not be completely saponified by lime without pressure and steam. It had been proved that saponification with lime was incomplete and could not yield the whole of the glycerin. If the saponification were done by means of alkalis, it was possible to extract the theoretical quantity of glycerin. He therefore felt justified in receiving cautiously the statement that there was only 6 per cent. of glycerin in butter, for others like himself had been able to get out 11 or 12 per cent. But it was to be remembered that Mr. Wanklyn's theory depended upon that experiment. If he had

obtained the full quantity of glycerin, there would have been no question of low fatty acids nor theory of iso-glycerin. Then, later on, in order to prove that his loss could not be glycerin, an experiment by boiling a dilute solution of glycerin in water was made. But it was well known, and he had proved long ago (see Analyst, Vol. XII, 65) that a dilute solution of glycerin could be boiled without loss of glycerin until the liquor had a strength of about 74 per cent. of glycerin. It was quite possible that Mr. Wanklyn's experiments agreed well with the deduction of Chevreul, and he would accept Mr. Wanklyn's statement that Chevreul did obtain a less quantity of glycerin from butter fat. But on the other hand Chevreul showed that butter fat contained some low atomic fatty acids which combined with a larger percentage of glycerin, and it followed therefore that butter must yield more glycerin than other fat. Mr. Wanklyn had said that butter contained 50 per cent. of glyceride and 40 per cent. of iso-glyceride of alde-palmitic acid and free fatty acids.

MR. WANKLYN: No, certainly part of that is iso-glycerides, and possibly some free acids.

MR. HEHNER, continuing: But it was proved that perfectly fresh butter fat was free from fatty acids. It, therefore, Mr. Wanklyn were not sure whether there were free fatty acids in butter fat, he was afraid he could not attach much weight to his other statements.

MR. WANKLYN: I said that there was 50 to 60 per cent. of glyceride, and that the remainder was either iso-glyceride or a mixture of iso-glyceride with free fatty acids. I do not pronounce an opinion as to whether there are any free fatty acids or not.

MR. HEHNER, continuing, said they had the author stating that there might be some free fatty acids. That was a matter easy of proof and their amount determined by any chemist in 10 minutes. Hence he was surprised that Mr. Wanklyn had not satisfied himself on the point. As to the analyses of the barium salt of alde-palmitic acid no chemist need be ashamed if, in two analyses of one and the same compound, he obtained figures so nearly approaching agreement as those between the two compounds whose analyses were on the board. Nevertheless, upon such a slight difference as 0.2 per cent. a theory was constructed. They had heard how the new fatty acid had been obtained by crystallising four times with an insufficient quantity of alcohol. But it was well known that it was quite impossible to obtain any fatty acid in a perfectly pure state by crystallising even many more times with alcohol. It was futile to attempt to obtain a fatty acid in the middle of a long series of acids by four crystallisations. It was an impossibility. But when they came to examine the matter they found that Mr. Wanklyn himself supplied the evidence that it was not one fatty acid that he was dealing with, but a mixture. He said that if he added an insufficient quantity of nitrate of silver to prepare the silver salt of the new fatty acid, his analysis did not agree with the quantity required by the formula; that was to say, by adding insufficient silver nitrate he had succeeded in fractionating the mixture of acids. Mr. Wanklyn, therefore, supplied the proof that this new fatty acid was not a homogeneous substance, but a mixture. He would like to have heard more of Mr. Wanklyn's views on soluble fatty acids. So much work had been done on them recently that anyone who now neglected what was considered the most important constituent of butter was, to say the least, rather out of touch with the subject. Dr. Wright had pointed out that there would probably be an iodine absorption. He himself would expect that there would be an enormous iodine absorption, judging by the alleged formula of the new fatty acid. In the case of butter fat, they had an absorption of about 33 per cent., and if Mr. Wanklyn had got 40 or 50 per cent. of this fatty acid, the iodine absorption should exceed by far the actual iodine absorption of butter fat. He was of opinion that the publication of Mr. Wanklyn's results was premature.

MR. A. H. ALLEN, as an old admirer of Mr. Wanklyn, and one accustomed to read his productions for the last

25 years, had listened with great interest to the paper just read. He had hoped to be instructed by an explanation and demonstration of the constitution of butter, and he might fairly say that Mr. Wanklyn had put the constitution of butter before them from a novel point of view. He (Mr. Allen) agreed with almost every word of scientific criticism that had fallen from Dr. Wright and Mr. Hehner; in fact, some of his own notes bore upon the same points, which were points which would naturally occur to one conversant with the matter under discussion, or with the accepted methods of working in organic chemistry. But there were some special points in addition which he would like to touch upon. In the first place, there was the deficient quantity of glycerin obtained by the treatment of the butter fat with lime. He fully agreed with Mr. Hehner that they had not had a satisfactory explanation of that point; and as Mr. Wanklyn did not appear to have ascertained the nature of the residue and proved that there was no undecomposed fat contained in it, he failed to see the value of the experiment. They had methods of estimating glycerin with fair accuracy; they had Mr. Wanklyn's own method, which had been referred to as the "moist combustion" process, but was better known as the permanganate method. That was a process based on the production of oxalic acid when the glycerin was oxidised by permanganate in alkaline solution. It was originally suggested by Mr. Wanklyn, improved by himself in conjunction with Mr. Fox, afterwards taken up by Benedikt and Zsigmondy, and subsequently modified by the speaker. He (Mr. Allen) could bear witness as to the admirable results obtained by that method in the analysis of fats. Working by this, which for brevity he would call the Wanklyn process, Benedikt and Zsigmondy obtained from 10.2 to 11.6 per cent. of glycerin to be formed by the saponification of butter, and he (Mr. Allen) had obtained 11.06 of glycerin from butter fat, while Liebshutz had isolated 13.75 per cent. Such results were very different from those brought before them that night by Mr. Wanklyn. Then, the author had referred to Chevreul. He did not, however, quote Chevreul direct, but through Gerhardt; and, unfortunately, only gave a figure obtained by the analysis of so-called butter-stearin, and not that yielded by butter-fat itself. By a method of analysis which was fully laid down in Chevreul's *Recherches Chimiques sur les Corps Gras d'origine animale*, published in 1823, a copy of which he held in his hand, Chevreul obtained from butter fat 11.85 per cent. of glycerin. So far, then, from the figure for glycerin obtained in 1823 by Chevreul being 6.2, it was 11.85. That, he thought, did away with anything like the deficiency of glycerin, which was the chief basis of Mr. Wanklyn's iso-glycerin theory. The author had adduced no single fact in favour of the existence of iso-glycerin or iso-glycerides, which could not be replied to and had not already been replied to in Mr. Wanklyn's presence. Then, Mr. Wanklyn had been content to lump together all the fatty acids of butter which were not soluble in water or alcohol, and had called them "alde-palmitic acid." It was a misfortune that Mr. Wanklyn had not used some of the good old tools of the chemical laboratory in his attempts to isolate this acid. For example, there was the invaluable method of fractional precipitation of the fatty acids as magnesium salts first employed by Reintz, and the well-known method of conversion into lead salts, and treatment of these with alcohol or ether, both of which methods had done good service in the past, and were admirably adapted for Mr. Wanklyn's purpose; and it seemed strange that one who was anxious to examine a new fatty acid should not have ascertained how this "alde-palmitic" acid behaved when made into a magnesium or a lead salt. There were other methods of research which would have afforded valuable information, such, for instance, as the determination of the bromine or iodine absorption of the acid. The amount of iodine absorbed by butter fat was well known to be small as compared with ordinary fats, and very much less than would be the case if the butter contained a large proportion of a body of the constitution of this "alde-palmitic" acid. This being the case, he failed to recognise any proof that this "alde-palmitic" acid existed as a distinct individual and not as a mere mixture of oleic acid with

palmitic acid and its homologues. Then, Mr. Wanklyn had said that he saw his way to detect 2 per cent. of adulteration in butter by these new researches. He (Mr. Allen) was glad of that, and hoped that he would tell the profession how to do so. Their present difficulty was not that they could not analyse within 2 per cent., but that the natural variations in butter were so great that 2 per cent. would not cover them. That was an important matter, and Mr. Wanklyn would have to consider it before he seriously determined to use his process for the detection of adulteration of butter. He could only say in conclusion that he was sorry Mr. Wanklyn had not supported his contentions by stronger evidence, which at present was missing, but which he hoped would appear when the interesting paper, of which they had just heard the abstract, came to be published.

Dr. W. JOHNSTONE had listened with interest to the paper, as he was at present working on the same subject himself, and the results obtained by him tended to establish the fact that there were two kinds of natural butter, one yielding 85.81 per cent. of insoluble fatty acids, a definite chemical compound, a compound triglyceride. The second kind was what one might term a compound complex triglyceride yielding insoluble fatty acids up to 90 per cent. He quite agreed with the author that oleic acid was not present in butter fat, and what was previously supposed to be oleic acid now proved to be iso-oleic acid, and might be summed up thus—

or lutro-methane tridacotic acid, which, when saponified, split up into tridacotic and butyric acid.

If one took the formula of a molecule of butter fat as follows:—

which theoretically gave 85.81 per cent. of insoluble fatty acids, and butyric acid 11.76 per cent. He had himself actually found 11.7 per cent. He would not go further into the matter then, as he proposed to enter into it in a paper at a later date. He agreed generally with the remarks of Mr. Hehner and Mr. Allen as to the estimation of glycerin, having found 12.23 per cent. against a theoretical yield of 12.30 per cent.

Mr. J. A. WANKLYN, in reply, said that he had listened to the criticisms on his paper with great attention, as he was not unprepared for them. In reading a paper on such a subject it would be tedious to publish all the details of the investigation, and in this instance much had been kept back. Dr. Wright had inquired what was the evidence upon which he relied as to the existence of alde-palmitic acid, and that he was dealing with a single substance. Part of the evidence was that he had 40 grms. of the substance, had made combustions and a baryta salt, and barium determinations. The homogeneous nature of the substance was shown by resorting to the method of fractional solution; no change in the equivalent of the acid was manifested. That, he thought, was fair evidence that he was dealing with a single substance. Having got this acid, the question arose whether the substance was palmitic acid or not. The evidence that it was not palmitic acid was the deficiency of hydrogen. That deficiency was eight-tenths per cent., and carefully made combustions did not err to that extent. Then he had backed that up by a determination of barium salt, carefully fractionated and prepared by the best known methods, in which he had got the theoretical result. In ordinary analytical work one could not distinguish between 21.17 and 21.31 of barium in a substance. But this was extraordinary work, using a large quantity of the material and adopting unusual precautions. In the preparation of the baryta salt he had employed a method which would give him a salt of great purity. As he had said, he proposed to work extensively on the alde-palmitic acid, though he had no doubt as to the composition of that body. In

naming it he was careful to say that it bore the same relation to palmitic acid that aldehyde did to alcohol. That was one way of saying that it differed by two equivalents of hydrogen. He had carefully avoided saying that it belonged to the oleic series; it belonged to another series altogether. Then he had noticed a number of little peculiarities that distinguished it from palmitic acid. He might mention, however, that it was not easily attacked by the method of limited oxidation. With respect to the question of determining glycerin from butter, judging from the criticisms he had heard he thought that the gentleman who had uttered them could hardly have understood what he had done. He had taken butter and hydrate of lime and heated them for a long time, with constant stirring. He had then treated with boiling water in successive portions, and then with boiling alcohol, using about a litre of those solvents to 60 grms. of material. That, he thought, was a good extraction. With regard to the volatility of glycerin he was quite prepared to admit that vapours might be seen escaping under certain circumstances; but that those vapours were glycerin was another question. If one could take a dilute solution of glycerin and boil it down without appreciable loss, that was proof that one need not fear loss of glycerin in the water-bath. With regard to the experiment of Chevreul, he had quoted from a well-known book. There was at the bottom of the page a statement of the amount of glycerin that Chevreul got from various fats. He had got the correct quantity from stearin of beef, and using the stearin of butter he got only 7.2. He (Mr. Wanklyn) had not referred to the original paper. With regard to the question of the iso-glycerin, he had been misrepresented as to the evidence on which he had stated its existence. Butter presented a remarkable reaction. If boiled with alcohol it gave no butyric ether; but if one put in potash it instantly gave butyric ether, and 2 or 3 per cent. of butyric ether distilled out. What could be the origin of that butyric ether? Potash decomposed butyric ether; and it was a remarkable thing therefore that potash and alcohol should give this ether by reacting upon anything. In order to explain the action, one must assume that the potash was consumed and that the butyric ether was produced as a secondary product. One took an iso-glyceride and saponified it, and iso-glycerin was liberated, and the iso-glycerin fell to pieces and gave water and a fatty acid. The evidence of the existence of the iso-glyceride was that reaction and the fact that one did not really get the theoretical quantity of glycerin from butter. He would conclude by saying that he had no doubt of the accuracy of the work that he had brought before the meeting.

Answering Dr. Wright's question as to the kind of butter operated upon, the butter employed eight years ago came direct from one of the best London dairies. He quite appreciated the necessity of making sure of the genuineness of the material, and Hudson Brothers had kindly placed some of their butter at his disposal for the continuation of the investigation. Mr. Walter Cole had also been kind enough to send him butter obtained by the Simplex process.

THE CYANIDE PROCESS FOR THE EXTRACTION OF GOLD FROM LOW GRADE GOLD ORES.

BY T. GRAHAM YOUNG, F.R.S.E., AND
WATSON SMITH, LECTURER ON CHEMICAL TECHNOLOGY IN
UNIVERSITY COLLEGE, LONDON.

In the Journal of our Society for the past year, 1890, pages 267 to 270, a very able paper is published containing an account by Mr. J. S. MacArthur of the process patented by himself in conjunction with the Drs. Forrest. He there (*loc. cit.* page 269) defines a difficult case untouched by any other kind of treatment, viz., that of an ore consisting of a complex mixture of silica, and the various compounds of iron, copper, lead, zinc, antimony, arsenic and sulphur.

with gold in the proportion of 10,000 parts of silica and sulphides to one part of the precious metal. He adds that such an ore is very much richer than the average auriferous ore, and the question is, "How can we best separate the one from the ten thousand?" The problem was to find some solvent which, unlike chlorine and mercury, would have a stronger affinity for gold than for sulphides, and the author concludes that the use of the alkaline or alkaline earthy cyanides solves the problem.

After small trials successfully performed, large trials also became successful in the author's experience. The first physical condition is stated as being that of a fine state of division of the ore to be extracted. In the case of tailings from the amalgamation process, these would not need re-grinding and might be treated as delivered.

The next condition, a physical one involving great chemical activity, was that of the zinc used for precipitating the gold from solution. It was used in a filiform condition, of minute and very thin parings of the bright metal. On and amongst this the gold is deposited as a very fine powder. The mass of zinc with gold powder is to be vigorously shaken in water, when the gold falls off, and the fibrous zinc particles are to be collected on a sieve.

From such sulphide ore as that above referred to, the author extracted 60 per cent. of the gold present by his cyanide process, whilst the bromine methods, he states, only extract from 10 to 50 per cent.

It is pointed out, finally, that whereas chlorination will only extract the gold and leave behind the silver, the cyanide method extracts both gold and silver, and the most of the silver in fact.

In the experiments we have to record, we have had the advantage of operating upon such ore as is actually treated by the MacArthur-Forrest process, and with cyanide and the zinc gossamer-like material as used in actual practice in the Cyanide Company's works, and the method has been put to as searching an examination as we could inflict in a chemical laboratory, following methods as likely as possible to be adopted in large scale practice.

The ground ore, as supplied, was agitated in one of the forms of milk agitating apparatus sold by Messrs. Kent in Holborn, for the production of butter. It is a simple revolving apparatus, in which glass jars are fixed, the caps secured by sheet india-rubber preventing any escape of liquid. Slow and continuous revolution was secured by the aid of suitable gearing and a gas engine.

The first thing to do was to determine the amounts of gold and silver in an average sample of the ore to be treated by the process.

It was found that in this ground ore were contained gold and silver in the proportions of—

Gold..... 0.95 oz. (troy) per ton of ore.
Silver..... 37.5 oz. (troy) per ton of ore.

Having thus determined the quantities of gold and silver in the ore to be extracted, by ordinary dry assay, it was now necessary to determine the strength of the cyanide of potassium. It was a dark-looking product and specially made for the purpose on a commercial scale. The stated strength was "from 60 to 70 per cent. of potassium cyanide." The strength found was 70 per cent.

It was now thought best to determine the degree of solubility of the gold and silver in the cyanide solution under the conditions obtaining in the ore. In other words, to ascertain what the relative amounts of gold and silver are which can be extracted from the ore in the ground state by solutions of the cyanide.

For the above purpose 1,000 parts of the ground ore were taken and 6 parts of crude 70 per cent. cyanide (4 parts of real cyanide). The cyanide was dissolved in 500 parts (all parts by weight) of water.

The mixture of ore and cyanide liquor was let stand for 20 hours, and then vigorously agitated for 6 hours and again let stand 16 hours. It was then filtered. The residue was not washed, but drained as thoroughly as possible by the filter pump.

To find how much was extracted by this treatment from the above filtered liquor, which we will call the 1st extraction, it was first passed through a divided box containing

in the first and last of its compartments granulated zinc, and in the middle compartment fine zinc turnings. This being unsatisfactory, the solution was further passed through a long funnel-shaped glass vessel containing fine zinc turnings and granulated zinc at top and bottom, exactly as used on the large scale. It was repeatedly passed through until colourless. As much as possible of the zinc was then distilled off from the mixed metallic gold, silver, and zinc, and the residue was examined for gold as to quantity.

It contained a quantity representing of—

Gold..... 0.121 oz. (troy) per ton of ore (1st extraction).

(The foregoing test does not represent all the gold actually extracted, since the attempt to use the divided zinc-box for precipitation of the metals failed, and lost some of the gold in the process. The box was then discarded in favour of the zinc funnel tube above mentioned.)

Now the residue left behind by the liquor, drained off to form the 1st extraction, was treated as in the previous case with a further 6 parts by weight of 70 per cent. cyanide, dissolved in 500 of water. The mixture was agitated well for 4 hours and then filtered as before. The liquid obtained formed the 2nd extraction. It was evaporated and the dry residue tested. It yielded amounts of gold and silver corresponding to—

Gold..... 0.157 oz. (troy) per ton of ore } 2nd extraction.
Silver..... 1.855 oz. (troy) per ton of ore }

The residue left behind by the liquor drained off on the second extraction, was once more treated with 6 parts of cyanide (70 per cent.) and 500 of water, and the mixture was agitated for 4 hours. The liquor, filtered and drained off just as in the previous cases, was evaporated, and the residue quantitatively determined as to gold and silver. The amounts of these metals yielded corresponded to—

Gold 0.006 oz. (troy) per ton on the ore } 3rd extraction.
Silver ... 1.864 oz. (troy) per ton on the ore }

No further extraction was made.

Under the circumstances given then, it was found that from 1,000 parts of ground ore the following amounts of gold and silver could be extracted by the use of 1,500 parts of a cyanide liquor containing 18 parts of solid crude cyanide of 70 per cent. strength (KCy) used. This was carried out in three extractions, for each 500 parts of cyanide liquor containing six of solid cyanide being used.

The progress of the solution and its extent are seen below:—

	1st Extraction.	2nd Extraction.	3rd Extraction.
	Oz. per Ton.	Oz. per Ton.	Oz. per Ton.
Gold.....	0.121*	0.157	0.006
Silver.....	..	1.855	1.864

* As pointed out above, gold was lost here, and so no calculation as to total gold extracted could be made in this experiment.

It is thus plain that the cyanide at once attacks gold and rapidly extracts it, whilst the attack on silver is slow and gradual. This will be seen better under Experiment 2, now to follow, in which the funnel tube is *uniformly* used instead of the box.

EXPERIMENT No. 2.

Another experimental trial was next made. In this 500 parts of ore were taken, 1 part of the 70 per cent. cyanide and 250 of water. After mixing, the substances were allowed to stand in mixture for 20 hours, and the mixture was then agitated for 6 hours and then let stand for 17 hours. Filtering with washing of the residue then followed.

Thus, extract (a) was obtained, and in it were found—

Gold 0.51 oz. (troy) to the ton of ore,
Silver 5.81 oz. (troy) to the ton of ore.

EXTRACT (b).

The residue left by Extract (a) was again treated with 1 part of the cyanide in 250 parts of water, with four hours agitation, and filtered. Thus Extract (b) was obtained, and from it were gained—

Gold..... 0·23 oz. (troy) per ton of ore.
Silver..... 7·78 oz. (troy) per ton of ore.

EXTRACT (c).

The residue left by Extract (b) was now treated with 2 parts of the cyanide in 500 parts of water, with four hours agitation.

Filtering and washing yielded Extract (c); from this were gained—

Gold..... 0·67 oz. (troy) per ton of ore.
Silver..... 8·15 oz. (troy) per ton of ore.

By the three Extractions (a), (b), and (c), 21·74 oz. of silver and 0·81 oz. of gold were thus extracted, and since the ore contains 37½ oz. of silver and 0·95 oz. of gold per ton, the above dilute cyanide has extracted—

Gold.	Silver.
Per Cent. 85·26	Per Cent. 57·98

The details of these extracts may be instructively tabulated thus:—500 grms. of ore yielded—

Water.	—	Silver.	Oz. per Ton.	Gold.	Oz. per Ton.
250	KCy. + 1 grm., stood 20 hours, agitated 6 hours, stood 17 hours	Grm. = 0·0888	5·81	Grm. 0·0079	0·51
250	+ 1 grm., agitated 4 hours.	= 0·1190	7·78	0·0085	0·23
500	+ 2 grms., agitated 4 hours.	= 0·1246	8·15	0·0011	0·07
By the three extractions—totals			21·74	..	0·81

FINAL EXPERIMENT.

The last experiment was one made for the purpose of ascertaining on a larger quantity of ore, if the precipitation of the precious metals by the zinc in fine turnings and granulated, is practicable, and under what circumstances.

For this, 2,000 grms. of ore, 30 grms. of the cyanide, and 1,000 cc. of water were taken. The mixture was agitated for 5½ hours, and let stand all night. (Agitating all night would be better, and would be adopted in practice. Moreover, washing and filter-pressing, in combination, would undoubtedly give very much better yields.)

It was found that the precipitated metals adhered rather tenaciously to the zinc. However, a process combining washing with agitation of the zinc would separate the precipitate tolerably completely.

Thus it was found that the amount of gold that could be separated from such zinc by washing and shaking = 0·560 oz. per ton, whilst the amount retained by the zinc after washing and shaking = 0·038.

At the same time, the amount of silver that could be separated from this zinc by washing and shaking = 21·42 oz. per ton, whilst that retained by the zinc after washing and shaking = 1·37; silver retained in solution after washing and shaking = 0·34, including a trace of gold.

Hence, supposing that the zinc can be used over and over again, and reckoning the amount of silver retained by the zinc as constant, then the amount of silver which can be extracted from the ore by a solution of such a strength as this latter, would be 61·6 per cent. of that contained in

the ore; whilst 63·09 per cent. of the gold contained in the ore would be extracted. However, this only represents the work of *one extraction*; no doubt repeated extraction would raise the amount for the gold to fully 85·4 per cent. (the figure obtained in earlier experiments). As the work of only one extraction 63·09 per cent. is unquestionably indicative of powerful, and hence valuable, solvent action.

With regard to the zinc treatment and cyanide left in the spent liquors, these, on evaporation, lost much cyanogen, but still left a residue which contained 18 per cent. on the total weight of the 70 per cent. cyanide taken. These liquors could hence be used again with further replenishment with cyanide.

We have much pleasure in thanking Mr. Oswald Hamilton for valuable assistance in the experiments recorded in this paper.

EXPERIMENTS BY BERTRAM BLOUNT.

In the early part of last year I was requested to ascertain the applicability of the cyanide process to the extraction of certain gold ores which had proved somewhat troublesome to treat by other methods.

Three ores were dealt with; they were from an Australian mine and had yielded unsatisfactory results when subjected to the ordinary process of amalgamation. Their assay values were—

—	I.	II.	III.
	Oz. dwt. gr.	Oz. dwt. gr.	Oz. dwt. gr.
Gold, per ton ...	0 8 11	0 19 14	1 0 22

In the first place a solution of potassium cyanide was made, containing 2·5 per cent. of the commercial salt, and 200 grms. of each ore treated with 200 cc. of this solution by shaking by hand in a stoppered bottle at intervals for several days. The extract was then filtered off, evaporated to dryness and the residue assayed. The figures obtained were—

I.	II.	III.
5·21	6·12	9·3

An attempt was then made to ascertain whether this indifferent result could be bettered by the use of a higher temperature and a larger proportion of cyanide in the following manner:—

100 grms. of ore No. III. were extracted with 200 cc. of the same strength cyanide solution, the extraction being conducted at the temperature of the water-bath.

The quantity of gold obtained was 3 dwt. 6 gr., a somewhat discouraging result.

Further experiments were instituted to determine the effect of more thorough agitation of the ore with the extracting liquor, and in these the strength of the cyanide solution was reduced to some extent.

In order to subject the experimental vessel to sufficient shaking, the following simple mechanical means was adopted: an old anemometer wheel was mounted in an oak block, the bearing being bushed with a bit of glass tubing and placed so that a stream of water from an ordinary tap on the water supply of the laboratory impinged upon the cups causing the rotation of the wheel. The bottle containing the ore and cyanide solution was slung to the wheel in such a manner that its centre of gravity approximately coincided with the centre of rotation and the whole arrangement was very fairly balanced and would remain in nearly neutral equilibrium in whatever position it was placed. Under these conditions a comparatively slight stream of water sufficed to

set the whole in vigorous rotation. The contents of the bottle were therefore agitated most efficiently. The stopper was, of course, secured by a piece of rag tied tightly down.

Carrying out an experiment with this apparatus, I treated 400 grms. of ore III. with 900 cc. of a solution containing 1 per cent. of commercial K_2O with 12 hours' agitation and 15 hours' rest, and extracted gold to the extent of 9 dwt. 11 gr. per ton.

In order to ascertain whether extraction (as far as the cyanide process could carry it) was complete, the same portion of ore was then treated again in exactly the same manner with the result that 1 dwt. 7 gr. was extracted.

The total amount of gold therefore obtained from an ore with an assay value of 1 oz. 0 dwt. 22 gr. per ton, was 10 dwt. 18 gr. per ton, or rather over 50 per cent. of the total gold.

This, though far from an ideal state of things, compares favourably with extractions by means of chlorine under pressure which I had previously executed on the same ore.

The comparatively high cost of the cyanide forms a cogent reason for endeavouring to utilise it to the utmost extent, and experiments were therefore undertaken to determine how far the liquors that had been used for the extraction of one batch of ore were available for the treatment of a second portion.

In these a sample of ore No. II., which had already been extracted with chlorine under pressure, and which had had its assay value thereby reduced to 6 dwt. 3 gr. per ton, was used.

Three portions of 200 grs. each were extracted successively with the same 100 cc. of cyanide solution, the liquor being in each case separated from the extracted ore by reverse filtration. The total extract was evaporated to dryness and assayed. It gave 3 dwt. 6 gr., or rather more than 50 per cent. of the total gold present. Assays of the tailings of each portion of ore showed that the extraction had proceeded to nearly the same extent in each, the third portion alone giving indications that the solvent action of the cyanide was becoming exhausted.

The conclusions that I draw from the experience thus gained are:—

1. A most important factor in the successful operation of the cyanide process is the amount of agitation to which the ore is submitted.

2. A strength of 1 per cent. is as efficient in securing extraction as one of 2.5 per cent.

3. To obtain 90–95 per cent. of the gold present in a refractory ore is rather too much to expect.

4. The efficiency is quite comparable with that of a good chlorine extracting process and the means considerably simpler.

5. Considering the high price of potassium cyanide, one of three conditions must be fulfilled to make any process depending on its use a commercial success. These are:—

(a) The same solution must be used repeatedly until its solvent powers are completely exhausted.

(b) A cheap and efficient method of recovering the cyanide from the liquors from which the extracted gold has been removed must be devised; or

(c) A greatly improved and cheaper method of producing cyanides must be invented.

The last is perhaps the way of achieving the object in view which is of the most general utility.

In conclusion I must record my acknowledgments to my assistant, Mr. S. Dickson, who has carried out these experiments under my direction.

DISCUSSION.

Mr. W. TRENSHAW said that he was interested in a syndicate which had taken up this process for the treatment of gold ores on the large scale in South Africa. The syndicate had purchased 10,000 tons from one mine for treatment by the process, and he had a cablegram in his hand which stated that at a cost of less than 15s. a ton they were extracting over 80 per cent. of the gold from an ore assaying about 16 dwt. In one case they were challenged to publicly treat almost pure pyrites. They did treat

1½ ton of it, and obtained a certificate from the challenger's expert that they readily took out 98.25 per cent. of the assay value. There were a few details in connexion with the process that were not yet published. When chemists were aware of these details they would acknowledge that the extraction of gold by cyanide was an almost perfect method. As to the question of the cost of the cyanide, when he mentioned that he had shipped over 7,000 lb. worth during the last four months at a cost of 1s. a pound, and that they were treating ore with only 2½ lbs. weight of cyanide per ton, he thought they would admit that it was not too expensive. He did not know of any other process that could compare with the cyanide process on the question of cost. Was there any other process which could effectually deal with refractory ores at a cost of under 15s. a ton?

Mr. W. F. ANDERSON wished to point out that the use of the word "ore" was not satisfactory in the case under notice. According to the statement on the blackboard, silver was present with the gold. If that were got out of quartz he would not call it an ore. Quartz required mechanically breaking up, and the two things therefore were very different. Chemists often spoke of gold ore; but there was no such thing, though there were plenty of silver ores. But gold was gold, even if in the heart of stone. Looking at the figures before them he would say that they represented a silver "reef," and that amalgamation was the proper process for it. He wished, however, that chemists would remember that quartz could not be called an ore; if it carried gold it was metallic gold. On the other hand, when iron pyrites carried gold, it required chemically splitting up to get the gold out.

Mr. CLAUDE VARTIN said that there was a great deal of truth in the remarks of each of the previous speakers; but at the same time Mr. Smith and Mr. Blount, and even Mr. Trenchaw, had spoken only of their experience of the process in connexion with the one class of ore that they had dealt with. He himself had carried out experiments on about 325 different classes of gold and silver ore and quartz, and had found that he had been able to classify the results under six different heads. The gold and silver existed under six different conditions, giving varying results as regarded treatment by cyanide. In its application to the tailings of the Johannesburg ores, the cyanide process seemed to leave but little to desire. The actual condition of the gold in the samples treated had not been referred to by either of the gentlemen who had spoken; but before one could investigate the result of any reagent on gold or silver contained in an ore one must ascertain how the gold existed in that particular ore. The word "refractory" was often used improperly. When he first went to Africa, he was led away by statements that a considerable portion of the gold was locked up in pyrites, and that it could be extracted only by converting the pyrites into ferrie oxide and treating by amalgamation or chemical methods. On returning to England he had made microscopic examinations of the Johannesburg ores, and found that they were not truly refractory. That was to say, he had not found any gold encased in pyrites after they were reduced so as to pass through a 60-mesh sieve. Therefore the condition of the grains of gold was practically metallic and free, in the sense that they were not embedded in the crystals of the pyrites or the quartz matrix. He doubted whether any system of amalgamation could deal with the gold to the bitter end; and if one could get a solvent to convert the gold into a soluble salt without materially taking up the sulphide of iron, then that was the best way of dealing with that particular class of ore. One part of the process was open to improvement, namely, the recovery of the gold from solution. It could be recovered by zinc, but an alloy of 99 of zinc and 1 of sodium gave far less trouble and almost a perfect precipitation. Speaking of the ore described by the author, he did not think the experiments were sufficiently practical. The ore was ground in such a way as no machine could produce it in large quantities, and on a large practical scale they would never get through the process, as leaching would be impossible. Properly worked, and with cheaper cyanide, the process would provide a

means of successfully treating enormous quantities of low-grade pyritic ores. Such ores existed all over the world, but were too highly pyritic to concentrate, too poor to smelt, and would not pay to amalgamate. He hoped therefore that chemists would do their part of the work by producing cheaper cyanide of potassium, and leave the application to metallurgists who had had actual experience on gold-fields and knew the real requirements.

Mr. J. S. MACARTHUR wished to thank his friend Mr. Trubshawe for going so fully into the matter from the commercial aspect, and for his particulars relating not to experiments on a small scale but to actual practical working, every word of which he could corroborate. The gentleman who had followed Mr. Smith had gone into some experiments that did not seem to be of much value, because of the insufficient agitation. That was a point that must be taken fully into consideration. Intermittent agitation would not do when the ore was very hard and non-absorbent. Wherever the gold was it was pretty far in, and the solution must have time to get at it, or be coaxed into contact with it. Before passing on, he would like to ask Mr. Smith why he did not in his experiments wash the cyanide solution out with water. He had given results on about 1,000 parts of ore and 500 of water, the whole thing being filtered. Naturally, the ore would contain about 20 per cent. of its weight of moisture, and with that the proportionate amount of gold. He thought that the experiments might have shown the working of the cyanide better if at the end of each stage there had been a complete washing. Mr. Blount had thrown some doubt on the statements as to the extraction of more than 90 per cent. of gold by the process; but he thought that Mr. Trubshawe had settled that point completely. With regard to the remarks that had been made as to the use of the terms "ore" and "quartz," he was not aware that the former term was limited to minerals containing metals in chemical combination, but thought it included free minerals also. But if a distinction were drawn between gold in the free state in quartz and gold in the pyritous state, it mattered not, for cyanide of potassium attacked the one as easily and with as much effect as the other. Mr. Vautin, too, appeared to have some trouble with the word "refractory." For his own part he adopted the simple plan of applying the term to any ore which, for whatever reason, would not yield its gold to the ordinary method of amalgamation. Mr. Vautin had also raised the question as to whether gold was chemically combined or mechanically held in pyrites.

Mr. VAUTIN: No, I meant that it was mechanically combined or encased in a crystal of the pyrites. It is still metallic, of course, but if you reduce the crystals so that they will pass through a 60-mesh sieve, that is sufficient to allow the metallic gold to pass out. What I inferred was that if a particle of metallic gold was still encased, the cyanide not being able to get at it, could not convert it into a soluble salt.

Mr. MACARTHUR, continuing, said that, however the gold might exist, the cyanide got at the great bulk of it. In one case it had done its work so thoroughly that they had extracted 98½ per cent. from an ore that was almost a pure pyrites—80 per cent. pyrites at least. That ore did not show gold even after being ground fine enough to pass through a 60-mesh sieve. He knew that many ores which on the most careful examination showed no free gold, did yield 90 per cent. at least to the cyanide method. Mr. Vautin had also spoken about the recovery of the gold from solution, and seemed to infer that that gave trouble. But it gave no trouble whatever. It went on with perfect smoothness and regularity, and they had no wish to improve it.

Mr. TRUBSHAWE wished to mention one other important fact, namely, that in some of their big trials of the process they had found simple percolation to be as effective as agitation. A lot of 500 tons just put through from one mine in that way had shown almost complete extraction.

With the view of demonstrating the value of the MacArthur-Forrest process, a public trial had been lately

conducted at the Salisbury Company's works near Johannesburg, on auriferous ores, tailings, and concentrates submitted for treatment. These trials, which were made on working quantities, and without preliminary roasting, gave the following results:—

Name of Company.	Dry Weight Treated.	Assay Gold per Ton.	Gold Extracted.
Salisbury	102 tons Buddle Head tailings.	oz. dwt. gr. 1 14 9	Per Cent. 82½
Do.	18,802 lb. concentrates ..	6 3 11	96½
Do.	10 tons pan residues.....	2 7 9	80½
City and Suburban.	13,440 lb. tailings.....	0 17 4	85½
Robinson	3,278 lb. ore	1 17 13	92½
Do.	3,078 lb. tailings.....	0 14 16	84½
Do.	2,744 lb. free-milling concentrates.	3 18 9	89½
Ginsburg Syndicate.	5,760 lb. pyritic ore.....	1 7 0	90½
Nooitgedacht Klerksdorp.	6,216 lb. do.	0 19 14	90½
Wilkinson Klerksdorp.	1,763 lb. do.	0 8 1	83½

Concentrates containing 80 per cent. of pyrites and assaying over 26 oz. of gold per ton, also proved amenable to treatment, over 98 per cent. of assay value being recovered by this process under special supervision.

	Assay per Ton.	Gold Extracted.
Results of 25 cwt. treated	Oz. dwt. gr. 26 6	Per Cent. 98½

Trials had also been made at the Cassel Company's works in Glasgow of the following refractory South African ores, which yielded the following results without roasting:—

"Edwin Bray," 95 per cent. extraction; "May Consolidated," 84 per cent.; "North Star," 94 per cent.; "Black Reef," 100 per cent.; "Klerksdorp," 100 per cent. (full extraction); "Nigel," 96 per cent.

The following results had also been obtained by this process at the Glasgow works in dealing with 22 tons of ore from the New Zealand Crown mines:—

	Gold.	Silver.
Weight of ore treated, } 215.15 tons..... } Assay contents	Oz. dwt. gr. 30 12 12	Oz. dwt. gr. 256 9 18
Actually extracted and recovered	26 14 11	219 7 11
Total average extraction	87½ %	85½ %

Dr. S. RIDEAL regretted that no systematic experiments had as yet been published, showing the relative chemical and economical values of the cyanide and older chlorine extraction processes. If different grades of ore were treated by the several processes no comparison was possible, but he thought that although apparently the cyanide process gave the best result with all kinds of ore, some of the old chlorine processes would be more economical under certain conditions.

The CHAIRMAN having suggested that Mr. Vautin might explain this point—

Mr. VAUTIN said that the advantage of having a solvent that would convert gold into a soluble salt without taking the sulphide of iron was of immense value. The difference

between the cyanide process and a chlorination process was that in the latter, before the chlorine could be applied, the sulphide of iron had to be converted into some form in which the chlorine had but little affinity for it. That necessitated furnaces, which on a gold-field entailed great expense, and limited the output of the mine to the roasting capacity of the furnaces. On the other hand, if the cyanide cost more than the actual cost of roasting, he would always advocate chlorination. It was easy, so long as one could banish the roasting when not actually necessary for removing the gold.

Mr. BERTRAM BLUNT wished to say a few words in reply to the criticisms of his own portion of the work. It might be quite right to say that, working on the small scale he had employed placed him at a disadvantage; but frequently it was the only means one had of investigating a process, and valuable results had been obtained in that way. He was afraid that until they all had big plants, they would have to go on with small experiments and modify their deductions accordingly. There was a good deal of variety in the accusations brought against him, one speaker having found fault with him for obtaining too much gold by grinding the ore too fine, while another thought that he had found too little in consequence of not agitating the ore sufficiently. It seemed to him, in fact, that the criticisms of one side went far to neutralise those of the other. A great deal of heavy artillery had been brought to bear upon a very simple communication. He did not suppose that his results or the general conclusions that he had drawn from them would be accepted as final; at the same time he had no reason to doubt the accuracy of his work. As to the complete washing of the ore after treatment with the cyanide, of course that took place. With regard to the degree of extraction claimed by the inventors of the cyanide process—while he did not wish to suggest that it was arrived at by the method he was about to speak of—he would mention that method in order to warn the unwary against placing too much confidence in the glowing statements that were not uncommonly met with. Some time ago a gold ore was treated by a certain process, and the extracted ore, together with the liquors resulting from the treatment, were sent to him. He assayed both, as well as the ore before treatment, and compared his results with the return made to him by the company owning the process. The quantity claimed to be extracted was 9 dwt. per ton, and the assay value of the ore was given as 10 dwt. per ton, the excellent yield of 90 per cent. of the total gold being thus apparently obtained. It was perfectly true that there was that quantity of gold extracted, but it was also true that the assay value of the ore was in reality nearly 20 dwt. instead of 10 dwt., thus reducing the percentage of gold extracted from 90 per cent. to about 45 per cent.—a vastly different result. On assaying the tailings the balance of the gold was found, thus confirming these figures. By conveniently understating the assay value of the ore the apparent efficiency of any process of gold extraction might be increased to any desired extent without committing the folly of overstating the absolute quantity of gold that could be extracted, and thereby counting detection.

Mr. WATSON SMITH having been called upon to reply, said that his friend Mr. F. Graham Young had a considerable interest in the matter, and but for severe illness would have been present to take part in the discussion. He had left to him the selection of the ore, which he believed to be a thoroughly representative one. In order to test the action of the weak cyanide solution on metallic gold, they had procured some pure gold leaf from Johnson, Matthey, & Co., and had found that the action was a surprisingly easy one. He knew that the price of cyanide was an important element in the practicality of the process, and had lately been told that it could not be produced under 2s. per lb. of 70 per cent. strength. Now that it seemed clear that brands of potassium cyanide could be obtained at half that rate and less, one of the principal difficulties of the process would be removed providing those brands whilst of diminished price were not also *pari passu* of diminished strength. The use of an alloy of zinc with a little sodium had been recommended as likely to produce good results in the precipitation

of the gold. The action of zinc under ordinary conditions was extremely slow; but in the gossamer condition its precipitating power was much increased though still slow, until some deposit had taken place. In reply to Mr. MacArthur, he would say that they did wash the specimen finally to get out the cyanide last remaining in the material before testing for gold and silver; and for a test of that kind he thought that the amount of gold and silver spoke very favourably for the process. Some processes could be carried out far better in the works than in the laboratory, for in the latter they could scarcely imitate the mechanical appliances used and so achieve the mechanical advantages obtained on the larger and practical scale. In conclusion, Mr. Smith alluded to a criticism of the process which had recently appeared in a letter to the "Engineering and Mining Journal," written by a gentleman who whilst claiming to have been the originator of the cyanide process, now appeared to dissent so bitterly from the method of which he was at first enamoured that he stated that he would now prefer to recommend extractors to employ an *aqua regia* process in preference to the cyanide process. If any argument could be based on this, it would be probably one of which the reagent recommended served as a reminder, *viz.*, one based on the fable of the "sour grapes."

MR. A. NORMAN TATE IN THE CHAIR.

THE SECTOR AND GREASE SPOT PHOTOMETERS, AND THEIR RESULTS.

(This Journal, 1891, pp. 18—20.)

By F. HURTER, F.R.S., AND V. C. DRIFFIELD.

(a.)—REPLY TO CAPTAIN ABNEY.

SINCE the last meeting we have constructed a photometer on the principle of Captain Abney's, and we are happy to be able to confirm every word he has said in his paper regarding the differences which result when one and the same negative is measured by his instrument and by our own. The density of the "fog," as we term it, is considerably smaller when measured by his instrument than when measured by ours, and we fully recognise that, although the higher densities measure only about 20 per cent. less by Captain Abney's photometer than by our instrument, his transparencies are much greater than ours.

The fact is, Captain Abney's transparencies are much too great and his densities too small. He can easily convince himself of this by measuring in his instrument the transparency of a piece of white paper, such as Rives, when he will find that it allows nearly 40 per cent. of the light to pass. We need not point out to him that this is far wide of the truth.

Such marked differences between the readings of Captain Abney's and our photometer must arise from causes which he ought to have had no difficulty in finding. He, no doubt, thought that these differences were entirely due to the scattering of the light, but, as we have shown, this is so trifling that it would never account for such discrepancies.

Whilst we measure the ratio of the amount of light which a given point (the grease spot) receives, first from the naked light and then through the negative, Captain Abney measures something entirely different. He measures the alteration in the transparency of a piece of paper which is brought about by placing a negative in front of it. This alteration he takes to be the measure of the transparency of the negative, but herein he is entirely mistaken. Had we thoroughly understood the construction of his instrument at the last meeting, we could at once have pointed out the cause of the differences, and could also have clearly shown his error.

We pointed out in our first paper that the laws of absorption, as we there stated them, hold good only for such substances as reflect but little light, and do not apply at all for other substances. One substance, for which the law does not hold good, is white paper. Now Captain Abney's method of measuring actually assumes that these laws do hold good for white paper, and that the density of a combination consisting of a piece of white paper and a negative is the sum of the densities of the paper and the negative taken singly. He assumes the density of the paper as a constant, and takes the alteration produced by placing a negative in contact with it as due to the density of the negative only; whereas, in reality, it is due to the density of the negative diminished by another very important factor, namely, the alteration in the transparency of the paper consequent upon the negative preventing reflection from its surface.

This law, which we have long known and which applies to all bodies we have so far tested, black as well as white, is the following: If O is the opacity of one and O_1 of another substance, and if R and R_1 are their coefficients of reflection respectively, then the opacity of the combination of the two is—

$$O \times O_1 \times (1 - RR_1).$$

It is the last factor, the existence of which Captain Abney did not recognise, which has led to the great differences in our results. It is a very important factor, and it wholly accounts for these differences.

If we measure, in our instrument, combinations of paper and negative, these differences vanish absolutely, and our readings are in complete accord with Captain Abney's. The order in which paper and negative are placed in our instrument is perfectly immaterial; whether the light passes first through the paper and then through the negative, or *vice versa*, the density of the combination is exactly the same, and the formula given indicates this.

But when we combine *three* things, say two pieces of paper and a negative, the opacity of the combination differs according to the order in which the three are used. Suppose, for example, we use two pieces of paper and a negative. Let O be the opacity of the paper (as measured in our instrument) and O_1 that of the negative. Let R be the coefficient of reflection of the paper, and R_1 that of the negative. The opacities of the three possible combinations will then be—

$$(1) \text{ Paper—paper—negative} = O^2 \times O_1 \times (1 - R^2) \times (1 - RR_1)$$

$$(2) \text{ Paper—negative—paper} = O^2 \times O_1 \times (1 - RR_1)^2$$

$$(3) \text{ Negative—paper—paper} = O^2 \times O_1 \times (1 - RR_1) \times (1 - R^2)$$

The first and the third are alike, but the second opacity is different. The reflective power of the negative being small compared with that of the paper, $1 - RR_1$ is greater than $1 - R^2$, and the opacity of the second combination is greater

than that of the other two. The influence of mutual reflection can thus be readily shown without measurements by combining, in different ways, two pieces of paper and a negative.

If, on a half-plate negative of uniform density, we place two pieces of paper on one side (1), two pieces on the other side (3), and, between these, one piece on either side (2), we then, in each case, look through two pieces of paper and a negative, but you will readily see that the combination (2), paper—negative—paper, is very much darker than the other two combinations (1 and 3), the reason being that the powerful mutual reflection between two papers is absent in the second combination.

Captain Abney is therefore entirely mistaken when he thinks that his figures represent the true transparencies of the negative; they represent, in fact, the transparency increased by the mutual reflection between the paper and the negative.

But Captain Abney says that his experiment on platinotype paper shows that his figures are more nearly correct than are ours. To this we answer: that is a mere coincidence. If he had made as many experiments in this direction as ourselves, he would have found that neither his nor our figures would suit all printing operations. Let the Captain, for instance, use the negative in an enlarging apparatus where it does not come into contact with the sensitive surface, and where mutual reflection is excluded, and he will find that the densities, as measured by his instrument, are absolutely useless and wrong by much more than 100 per cent.; whereas ours are very nearly correct—not quite, because even the densities of negatives as given by our instrument are too small; a ferrous oxalate developed plate even offering more resistance to the blue rays than to the others.

Captain Abney has evidently not studied the question as carefully as we have done, and he has not considered the mutual reflection at all. The principle of his apparatus is wrong, and in attempting to avoid the trifling difficulty of "scattered light," he has fallen into the error of disregarding the much more important factor "reflected light."

We are certain that our instrument gives, as nearly as it can be measured, the correct density of a negative free from all other complications, and, so far, it is the only one which has proved itself a reliable and handy substitute for a chemical balance in photographic researches.

(b).—REPLY BY CHAPMAN JONES.

I have to thank Messrs. Hurter and Driffield for giving me this opportunity of replying to the section of their paper that has an immediate reference to me. I do not consider that they have correctly represented my position in the matter, nor the proper bearing of the particular experiment which they deem of so much importance.

In a paper by Messrs. Hurter and Driffield, published in the May number of the Journal of the Society of Chemical Industry, 1890, p. 455, the authors made several assertions concerning the development of photographic sensitive surfaces which are at variance with every-day experience. Some of these I combated in a paper read before the Photographic Society of Great Britain, and published in the November number of that Society's journal. To this paper and Messrs. Hurter and Driffield's accompanying reply I must refer those who are interested in the matter. It is sufficient to state here that I showed evidence against Messrs. Hurter and Driffield's assertions, and demonstrated that every experiment made by these gentlemen that I knew of either confirmed or was agreeable with the views I upheld. The particular experiment that they have just criticised is a comparatively unimportant item in the argument. I have dealt with this experiment in my paper, and have there met the hypothesis about the inequalities of the coating of the plate, and quoted

from Messrs. Hurter and Driffield's correspondence what is practically an admission that there is such a difference between the two plates as a partial remedying of over-exposure would effect. The only new point now raised is the objection to my method of averaging, based on the statement that all the highest ratios lie on one side of the plate. I would point out that the group that has been indicated as not including any of the high marginal ratios, gives the same average as the adjacent group, which includes two of these high ratios. Messrs. Hurter and Driffield appear to have no objection to averaging in groups of four instead of five, as this gives one high marginal ratio to each group, and they state that the figures so obtained fail altogether to support my claim. I had rejected this method as less impartial than the other. Both series of figures show that the ratios rise as the densities increase:—

Averages.	
In Groups of Five.	In Groups of Four.
1.48	1.47
1.54	1.51
1.54	1.57
1.69	1.58
..	1.59

(C.)—REPLY TO MR. CHAPMAN JONES BY F. HURTER, PH.D., AND V. C. DRIFFIELD.

In reply to Mr. Chapman Jones' remarks, we much regret if we have in any degree misrepresented him; but we are completely at a loss to understand in what way. The growth of the density ratios, with which he is so deeply impressed, is fully accounted for by a thin place in one of the plates. This place is marked by the lowest density ratio in square No. 3, from which point it will be seen the density ratios increase in all directions. We have previously pointed out to Mr. Chapman Jones that a *thickly* coated plate does not, by any means, imply an *evenly* coated plate.

He has throughout professed to regard our results from the point of view of the practical photographer, and granting that he has, in his experiment, remedied over-exposure to the full extent he claims, he has brought about a degree of improvement which the eye alone could never discover, and which, therefore, to the practical photographer would count for nothing.

RELATION BETWEEN PHOTOGRAPHIC NEGATIVES AND THEIR POSITIVES.

BY F. HURTER, PH.D., AND V. C. DRIFFIELD.

THE photo-chemical investigations which we had the honour to bring before this Section were undertaken with a view to render photographic operations more certain and reliable than they are at present, and by this communication we wish to direct the attention of photographers to the advantages of scientific procedure over rule of thumb manipulation. We propose to produce, by contact printing, a negative from a transparent positive, and from a negative two positives; the three being produced upon three entirely different plates. We hope to prove that we can produce the best possible result upon these plates with certainty, without making any calculations, and that, although a knowledge of logarithms is necessary for the appreciation of our theory, no such knowledge is required to carry out our practice, which indeed is simplicity itself.

In order to be successful in photographic operations it is essential to know exactly the properties of the plates we intend to use. We must know their sensitiveness to light, their behaviour during development, and their behaviour to negatives, if transparencies and secondary negatives are to be produced.

We think it well shortly to recapitulate as much as is necessary of what we have already published, so that the principles on which our operations depend may be properly understood.

We have shown that when light acts upon a sensitive film, the growth of the density of the resulting image (i.e., the amount of reduced silver) is at first proportional to the intensity of the light, but that, owing to the decreasing amount of unaltered silver salt, the density grows less rapidly with prolonged exposure; a period now supervenes when it ceases to grow at all, and at last it decreases if the exposure be unduly prolonged. We have shown that for every plate there exists a range of exposures during which the growth of the density is proportional to the logarithm of the exposure, and this range we termed the "period of correct representation."

Now, what we aim at, in studying our plates, is to ascertain this range of exposures. The method of doing so is simple. We expose different portions of a plate to the light of a standard candle placed at a distance of one metre from the plate for various periods of time, every successive exposure being double the previous one. After development we measure the amount of silver reduced by our photometric method.

The densities thus obtained, when plotted on a diagram, furnish the "characteristic curve" of the plate. We refer you to diagram No. 6, which shows the characteristic curves of the Wratten "ordinary" and "instantaneous" plates, which we intend to use to-night.

RELATION BETWEEN PHOTO-NEGATIVES AND THEIR POSITIVES.

The lower horizontal scale is a scale of exposures, the vertical scale the scale of densities. The divisions of the exposure scale are similar to those of an ordinary slide rule. The divisions of the vertical scale are all equal, and the distance between 0 and 1.00 on this scale is exactly equal to the distance between 1 and 10 on the exposure scale.

In order to save trouble we have had skeleton diagrams with these scales lithographed, and members are welcome to copies. They are exceedingly convenient for plotting characteristic curves and making other memoranda of experiments.

It will be seen that the two curves on this diagram are very similar, but they are situated on different portions of the exposure scale. The one plate requires much shorter exposures for the production of the same density than the other. The more to the left of the exposure scale the curve is situated, the faster is the plate.

The curve itself consists of three distinct portions. The lower strongly curved portion is the period of under-exposure; the middle portion, almost a straight line, is the period of correct representation; the upper curved end is the period of over-exposure.

The middle or straight line portion of this curve embraces the only useful range of exposures, and the only one which interests us to-night. If we produce this straight line until it intersects the scale of exposures, the point of intersection marks a particular exposure, viz., the shortest, which will produce a density very nearly at the beginning of the period of correct representation. We have shown that this point of intersection is practically independent of the length of time of development.

Diagram No. 7 shows the divisions of the characteristic curve into three periods more clearly. The curves on this diagram are two of the infinite number which are all characteristic of the same plate, and which result from differences in the length of time of development. The shorter the time of development the less inclined is the straight line, and as development is prolonged, the more inclined does the straight line become, but, whatever the inclination, it would still intersect the exposure scale at the same point.

It is important to know what length of time development must last in order to reach any particular inclination of this straight line. We therefore develop the plate, when determining its speed, for an exact time at a specified temperature, and note the inclination of the line by drawing through the point 1,000 on the exposure scale, a line parallel to the straight part of the characteristic, noting its point of intersection with the density scale. This gives us the value of the tangent of the angle of inclination, which value we term the "development constant." Knowing the value of this constant for one time of development, we can approximately determine the time it would take to reach any other constant, but our results in this respect are not yet sufficiently complete for publication.

We may here say that, in our first paper (9, 467), we gave a formula for the calculation of the development factor γ , which, we regret to say, was accidentally inverted. It should stand—

$$\gamma = \frac{D_2 - D_1}{\log E_2 - \log E_1}.$$

In our former publication we have shown how we utilise the information obtained by the simple experiment with a candle for the production of negatives in the camera; we now proceed to show how we utilise it for the production of positive transparencies and secondary negatives.

The production of secondary negatives may not be considered by many as of importance, but other researches we have made have clearly shown to us that one and the same negative is not equally suitable for all printing processes, and that a negative yielding a good ordinary silver print is generally incapable of giving a first-class enlargement on bromide paper. There are therefore cases in which the production of secondary negatives of special qualities is most desirable.

Let us now imagine a sensitive plate behind a negative illuminated by a light of known intensity. For simplicity's sake let the negative have only one or two different opacities. Let the opacities of the negative be 40, 20, and 10, then we should expect the plate to be illuminated behind the negative with $\frac{1}{40}$, $\frac{1}{20}$, and $\frac{1}{10}$ the original intensity

of the light. Experiment reveals, however, that this is not so, but that the results of exposures to the light behind the negatives are greater than those which would be produced by $\frac{1}{40}$, $\frac{1}{20}$, and $\frac{1}{10}$ of the original light intensity. The reason for this is not far to seek. When the light shines on the plate directly, say about 70 to 80 per cent. of the light is reflected by the plate into space. When a negative is placed in front of the plate the light is similarly reflected by the sensitive surface, but a considerable portion of it is at once reflected back again by the two reflecting surfaces of the negative, so that behind a negative less of the light transmitted by it is lost by reflection from the sensitive film, and consequently more work is done on the film than would be the case if the same intensity of the light were to act upon a film free to reflect.

Suppose the naked film were exposed to light of unit intensity. It would reflect into space the fraction R of light. Of the rest $(1 - R)$, some would be absorbed and some would pass through the plate. If, however, a negative be placed in front of the sensitive film, then the fraction R of the light cannot be reflected wholly into space; a portion of it is reflected back again upon the film, and if the coefficient of reflection of the negative be r , the amount of light which is thus returned to the film is Rr . Secondary, tertiary, &c. reflections add small amounts R^2r^2 , R^3r^3 , &c. to this. The result is that the effect of unit light coming through a negative is greater than the effect of unit light when the film can reflect freely, and is represented by the amount—

$$1 + Rr + R^2r^2 + R^3r^3 + \dots = \frac{1}{1 - Rr}.$$

or, what is the same thing, the opacity of the negative appears to be reduced by a fraction $(1 - Rr)$. It will therefore be seen that the same negative will give different results upon different printing surfaces, according to the amount of light which these surfaces reflect.

There is still another point to be considered. When we measure the opacity of the negative, we measure it chiefly to the yellow rays of the lamp, whilst those rays are least active upon the plate. The opacity of the negative to the blue rays is in all cases we have tested greater than the opacity to the yellow rays.

These considerations will explain why, when a negative is used for contact printing, its opacity must be considered as less than that indicated by our instrument; and when it is used for enlargement the opacity must be considered as greater than that measured in our instrument, because, in the one case, the sensitive surface cannot reflect freely, whilst in the other it does so.

The exact amount, therefore, by which we have to increase or decrease the value of the opacity of the negative depends upon the reflection of the film, upon its sensitiveness to different portions of the spectrum, and upon the colour of the negative.

If it were not for these corrections the relation between a negative and its positive could be at once deduced from the formula we gave in our paper for the calculation of the amount of silver deposited for a given exposure. This formula was, for the period of correct representation—

$$D = \gamma \log \left(\frac{1}{i} \right).$$

We should have to consider that in this formula the intensity of the light I is reduced by the negative, and we should have to divide I by the opacity of the negative, which in logarithmic calculation means deducting the logarithm of the opacity from the logarithm of the intensity of the light. But the logarithm of the opacity is the density as measured by our instrument, which density we simply subtract, and, in order to prevent confusion, we mark the densities of negatives, including the fog, by N , and the densities of positives by P . The equation which results, if we introduce at the same time the correction α of the negative density for the reasons just explained, stands thus:—

$$P = \gamma \left[\log \frac{1}{i} - \alpha N \right]$$

and this equation represents the general relation between a negative and its positive. P is the density of the positive

produced behind the negative of density N upon a plate of inertia i by means of the light intensity I in the time t .

The coefficient a which converts the density, as measured, into the printing density is, for negatives, developed by ferrous oxalate, usually a fraction; for pyro-developed negatives it is generally nearly 1, if the negative be used for contact printing; but when the negative is used for enlarging, the factor a , which changes the usual density of the negative into printing density, is always greater than 1, even for negatives developed with ferrous oxalate.

The method we have adopted as the simplest for finding the printing factor a is as follows, and is illustrated by diagram No. 9. We must assume that we have already

made a speed determination of the plate of which we wish to determine the printing factor, and that we consequently know the extent and position of the straight line which indicates the period of correct representation. We proceed to make two more exposures which, so long as they fall within the correct period, should lie as widely apart as possible. In our example we have given exposures of 5 and 40 C.M.S. We next take a negative of a uniform density of, say, about 1.0. Our object is, through this negative, to produce upon the plate under examination a density which shall lie somewhere between the densities which will result from the two direct exposures already given. The geometrical mean of 5 and 40 is, roughly, 15, and we therefore aim to produce a density behind the

Diagram No 9

negative (the total density of which is, in our example, 0.985) equivalent to a direct exposure of 15 C.M.S. We calculate the necessary exposure thus:—

$$\log T = \log 15 + 0.985$$

$$T = 145.$$

We now give this exposure of 145 C.M.S. through the negative and proceed to develop the resulting plate, together with that produced by the direct exposures of 5 and 40 C.M.S. Having measured the resulting densities, we mark upon the exposure lines 5 and 40 of one of our skeleton diagrams those densities (exclusive of fog) which result from the two direct exposures, in our example 1.010 and 1.965 respectively. Through these two densities we draw a straight line which coincides with the correct period of the plate. In our example the density produced through the negative is 1.730, exclusive of fog; this we mark on the density scale, and draw through it a horizontal line intersecting the straight line we have already drawn. Through this point of intersection we draw a perpendicular and mark the point of its intersection with the inertia scale. This point of intersection gives the direct exposure to which an exposure of 145 C.M.S. through the negative is equivalent, in this example 24 C.M.S. We have now merely to deduct $\log 145$ from $\log 145$ and divide the result by the density of the negative used, and we obtain the printing factor a —

$$\frac{\log 145 - \log 15}{0.985} = 0.79$$

That this mode of converting the visual density into the printing density is correct practically, even for the errors caused by mutual reflection, is best proved by experiment.

Having measured in our instrument the densities of a negative with a number of different but uniform tints, and found the densities to be N_1, N_2, N_3 , &c., we can calculate the time of exposure necessary to produce, behind each tint, exactly the same positive density if once we know the factor a .

The times of exposure are given by the equation—

$$\log t - aN = \text{constant}.$$

We have made many such experiments, of which we quote one as an example. Behind the negative densities N it was proposed to produce positive densities corresponding to 15 C.M.S. direct exposure upon a plate known as "Barnet ordinary," the printing factor for which is $a = 0.665$. The following table shows the calculations and results, the time of exposure being calculated by the formula—

$$\log T = \log 15 + 0.665 N.$$

N .	$a N$.	$\log T$.	T .	P .
1.250	.8319	1.9939	98.6	1.300
.985	.6647	1.8177	65.7	1.310
.920	.6128	1.6149	41.2	1.330
.730	.4863	1.4353	27.2	1.285
Mean.....				1.306

It will be seen that the densities of the resulting positive were as nearly equal as they could possibly be made. Such experiments, of course, require an exact knowledge of the factor α .

The mode of correcting the visual density for mutual reflection and colour can, however, be proved correct in another way, which does not involve a previous knowledge of the factor α .

The formula $P = \gamma (\log. \frac{I t}{i} - \alpha N)$ becomes by transposition $P + \alpha \gamma N = \gamma \log. \frac{I t}{i}$. Since when exposing a sensitive plate behind a negative, the intensity of the light I in front of the negative, the time of exposure, and the inertia of the sensitive plate are all the same, the sum $P + \alpha \gamma N$ must be the same for any corresponding points of the negative and positive. If, therefore, we print a positive from a negative, ensuring such exposures as fall within the period of correct representation, measure the resulting densities, and then form the sum $P + \alpha \gamma N$, this sum must be constant. Since $P + \alpha \gamma N = c$ is the equation of a straight line, we can show this property graphically without knowing $\alpha \gamma$. We simply choose the densities of the negative as abscissæ, the densities of the positive as ordinates, and join the points which should form a straight line if the proposition is correct. We give a few experiments of this description.

Experiments made in 1887. $P + 1.6 N = 3.083$.

Negative Density, N.	Positive Density, P.	$P + 1.6 N$.	Error.
0.700	1.969	3.080	- .003
0.900	1.680	3.120	+ .047
1.010	1.480	3.096	+ .013
1.223	1.113	3.066	+ .013
1.285	1.010	3.060	- .023
1.360	.850	3.020	- .063
1.550	.530	3.010	- .073
1.660	.417	3.073	- .010

Experiment No. 2. $P + 1.5 N = 2.530$.

Negative Density, N.	Positive Density, P.	$P + 1.5 N$.	Error.
0.700	1.470	2.520	- .010
0.900	1.140	2.490	- .040
1.010	1.007	2.562	+ .032
1.223	.637	2.491	- .039
1.285	.547	2.474	- .056
1.360	.410	2.430	- .100
1.550	.270	2.595	+ .065
1.660	.190	2.680	+ .150

This experiment being made with a slow plate the last few positive densities fell into the period of under-exposure. It must not be forgotten that all the formulæ so far given only apply to the period of correct representation.

The following more recent and more complete experiment has been made the subject of a diagram to illustrate the graphic mode of proving that the actual exposures a plate receives behind a negative are accurately represented by our formulæ.

To diagram No. 8 the abscissæ are the densities of the negative, the ordinates the densities of the positive, and it

will be seen that all the points can be joined by a straight line, which proves that the printing densities of the negative were absolutely proportional to the densities as measured by our grease-spot photometer; were it otherwise the points would have been situated on a curve. The plate used for the positive was a Paget "Phoenix;" its constants had all been determined by special experiments, so as to make it possible to calculate beforehand the densities which

ought to result. These constants were: Inertia = 6.11 C.M.S., printing factor $\alpha = 0.577$, development factor, for $4\frac{1}{2}$ minutes at 60° F., $\gamma = 1.03$. Behind a measured negative one of these plates was exposed for 134 seconds to a standard candle at 1 metre distance. The table shows the numerical results. The calculated densities are obtained by the formula—

$$P = 1.03 [\log. \frac{134}{6.11} - 0.577 N]$$

Negative Density (observed).	Positive Density (observed).	Positive Density (calculated).
0.165	1.270	1.285
0.255	1.225	1.230
0.440	1.120	1.120
0.670	.990	.982
0.98	.805	.800
1.28	.625	.620
1.57	.445	.450
1.81	.315	.300

These experiments clearly demonstrate the general relation between the negative and its positive, and show the truth of our formulæ for correct exposures.

But nothing will be so convincing of the truth of these formulæ and measurements than an ocular demonstration. If, by carefully timing both the exposure and the development, we succeed in making the value of the product $\alpha \gamma$ numerically equal to 1, then the formula becomes—

$$P + N = \text{constant.}$$

Since P and N represent the visual densities of the negative and positive, this formula really tells us that, if such a positive is placed in juxtaposition with its negative, the picture should vanish totally; we ought to perceive nothing but a uniform tint all over the plate, since on every spot the sums of the positive and negative densities are alike. We show here a negative and positive, at present fastened together, which will prove this special case of our formulæ, the only one which can be proved so readily. But it must not be supposed that every positive and every

negative will do this; it is only when exposure and development have been carefully timed that this result is obtained.

We must now refer you again to diagram 8. If, on this diagram we produce the straight line until it intersects the scale of negative densities, the point of intersection would indicate the smallest negative density through which the standard candle, at one metre distance, would have been just unable to affect the plate in the 134 seconds given.

This leads us to the rule by which we ascertain the exposure necessary to produce with certainty a good positive transparency upon a given plate.

We first of all measure the highest density of the negative which we then correct with the factor α for the particular sensitive plate, and, knowing the inertia of the plate, we take care that the exposure shall be such that, behind the highest density of the negative, the plate shall receive an exposure at least equal to the inertia. By our formula the necessary exposure would be—

$$\log. T = \log. i + \alpha N.$$

But we do not need to make the calculation at all. Thanks to the arrangement of our diagrams, we need only take into a pair of compasses the printing density of the negative measured on the density scale, and measure from the inertia of the plate the same distance to the right on the exposure scale, and we read off at once the necessary exposure.

If the positive is to serve for the reproduction of a negative, it is absolutely necessary to continue development until the difference between two densities, say the extremes, is equal to the difference of the corresponding extremes in the negative. If the development is too short the resulting positive may look better, but it will not yield a good secondary negative.

By variations in the time of development it is possible to produce secondary negatives in which the scale of tones is either contracted or extended, and this function of development is of the utmost value in the production of special negatives for special printing processes.

It is undoubtedly a difficulty that, with one and the same negative, we have to multiply its densities as measured photometrically with different factors according to the plates we use with it. For negatives developed with ferrous oxalate the factor varies from about 0.6 to 1.0. We find it, however, sufficient for practical purposes to use the factor 0.8, but, of course, it is always better to ascertain the correct factor by experiment.

All this appears to be very complicated, but in actual practice it is very simple, as we shall now proceed to show. At the last meeting we produced, from a positive, a secondary negative, and we ascertained the necessary exposure as follows.—The highest density of the positive, as measured in our instrument, was 2.70, the printing factor α for the plate we used (Barnet) was 0.665, so that the highest printing density was $0.665 \times 2.70 = 1.7955$. We measured the amount, 1.795, or practically 1.800, with the compasses on the density scale, and carried this distance off on the exposure scale from the point 1.3 (the inertia of the Barnet plate). This indicated an exposure of 81 seconds, and this exposure we gave, the result proving it to have been correct.

To night we propose to conclude our paper by producing two positive transparencies by contact printing on two plates of considerably different sensitiveness. The plates we shall use are Wratten "Ordinary" and "Instantaneous." The highest density of the negative we shall use is 2.385, and if you will refer to diagram No. 6, you will see how, from this density, we arrive at the exposure necessary for the two transparencies. We first of all multiply the density 2.385 by 0.8, and this gives the effective printing density 1.90 for the Wratten plates. We measure with compasses 1.9 on the density scale, and applying the compasses to the inertia of each plate, we read off, on the inertia scale, exposures of 87 and

1,200 C.M.S. for the "instantaneous" and "ordinary" plates respectively.

We will expose the "instantaneous" plate first, but instead of giving an exposure of 87 seconds at a distance of 1 metre from the candle, we will, to save time, give 43½ seconds at a distance of 0.707 of a metre. Having made this exposure, we will proceed to expose the "ordinary" plate. The exposure indicated is 1,200 C.M.S., which amounts to 20 minutes, and, as we do not wish to tax your patience to this extent, we will show you how we curtail a too lengthy exposure. Instead of using a candle, we will take a paraffin lamp, and we will find the distance at which it must be placed from the plate to be equal to 100 candles at 1 metre distance. To do this we hold a piece of white cardboard in the place of the sensitive plate, and, by means of a simple shadow photometer, we adjust the position of the lamp until its light is equal in intensity to that of 100 candles at a distance of 1 metre. We view the shadows through a piece of green glass in order to obviate the colour difficulty. We have now increased our light one hundred-fold, and the exposure we must give is consequently 12 seconds.

(The resulting positives showed that these widely different exposures were perfectly timed, and there was nothing whatever to distinguish one from the other.)

In the discussion that followed Mr. A. WATT remarked that he was glad to be able to confirm the experiment by which the authors of the paper had shown that the production of a perfect negative is possible. Believing that this proved the general accuracy of their researches, he had repeated the experiment, and had succeeded in obtaining a negative which, when placed in contact with its positive (transparency), and viewed by transmitted light, showed a nearly uniform density all over the plate, and only a faint trace of an image. The combined positive and negative was shown to the meeting.

Meeting held Wednesday, 4th February 1891.

MR. A. NORMAN TATE IN THE CHAIR.

THE DECOMPOSITION OF STRONTIUM CARBONATE BY HEAT.

BY JAMES T. CONROY, B.Sc., SHERIDAN MUSPRATT SCHOLAR, UNIVERSITY COLLEGE, LIVERPOOL.

THE accounts to be found in our text-books and other works with regard to the decomposition of strontium carbonate into strontia and carbonic anhydride when heated vary so widely that I thought it would be of interest to study the conditions of decomposition especially in reference to the quantitative determination of strontium as the carbonate.

That there was room for such an investigation will be readily admitted when such contradictory statements as the following are to be found:—

SrCO_3 , heated in a platinum crucible over a gas blowpipe is almost completely converted into oxide after about 20 minutes (Valentine).

SrCO_3 ignited with access of air is infusible, but when exposed to a most intense heat it fuses and gradually loses CO_2 (Fresenius).

For the purpose of examination pure (so-called) strontium carbonate was obtained, which on analysis, however, was found to contain 1.5 per cent. of calcium carbonate.

To purify this the carbonate was converted into the nitrate, and the crystals of nitrate, after powdering, extracted with warm alcohol in which calcium nitrate is soluble.

The insoluble strontium nitrate, after washing with alcohol, was drained at the pump. The product, which, when examined in the spectroscope, showed none of the calcium lines, was dissolved in water and strontium carbonate precipitated by the addition of ammonium carbonate. The precipitated carbonate was washed by decantation and finally on the filter until the filtrate ceased to give a reaction with Nessler's reagent, and the product dried at 150°–170° C. The carbonate thus obtained, after heating to dull redness over the Bunsen to remove any moisture still remaining, was analysed, the carbonic anhydride being estimated by absorption and the strontium oxide (1) by direct conversion of the carbonate into the sulphate in a platinum crucible, and (2) by precipitation as strontium sulphate in presence of alcohol.

—	Percentages.	Mean.	Theory.
SrO (by direct conversion)...	70·35	70·32	70·17
(by precipitation)	70·29		
CO ₂	..	29·72	29·83
		100·04	100·00

[Sr = 87·5, O = 16, C = 12.]

From this it appears that the precipitated carbonate was very slightly basic.

Behaviour on Heating.—The carbonate was heated, in quantities varying from 1·25 to 0·25 grms., in a platinum crucible over the Bunsen, in the muffle and over the blast with the following results:—

TABLE I.—BEHAVIOUR OVER THE BUNSEN FLAME (TEMPERATURE ABOUT 800° C.).

Experiment I.			Experiment II.			Experiment III.			Experiment IV.			Experiment V.		
Weight of SrCO ₃ taken (in Grms.).														
1·2770			·8435			·7380			·4120			·2426		
Total Time of Heat in Hours.	Total Loss of CO ₂ in Grms.	Loss per Cent.	Time in Hours.	Loss CO ₂	Loss per Cent.	Time in Hours.	Loss CO ₂	Loss per Cent.	Time in Hours.	Loss CO ₂	Loss per Cent.	Time in Hours.	Loss CO ₂	Loss per Cent.
$\frac{1}{2}$	·016	..	$\frac{1}{2}$	·0125	..	$\frac{1}{2}$	·0108	..	$\frac{1}{2}$	·0055	..	$\frac{1}{2}$	·0035	..
$\frac{3}{4}$	·0165	..	$\frac{1}{2}$	·0125	1·48	$\frac{1}{2}$	·0108	1·46	$\frac{1}{2}$	·0055	..	$\frac{1}{2}$	·0035	..
$6\frac{1}{2}$	·017	1·41							3	·0055	..	$3\frac{1}{2}$	·0033	1·44
									4	·0055	1·33			

That the loss in these cases is constant, notwithstanding the varying lengths of time during which the crucibles were heated and the different sized flames employed, show that

the loss (1·45 per cent.) is entirely due to moisture in the precipitated carbonate,

TABLE II.—BEHAVIOUR OVER THE BLAST (TEMPERATURE 1050°–1100° C.).

I.			II.			III.		
·831 Grm. Dry SrCO ₃			·630 Grm. Dry SrCO ₃			·2321 Grm. Dry SrCO ₃		
Total Time of Heat in Hours.	Total Loss of CO ₂ in Grms.	Per Cent., Loss CO ₂	Time in Hours.	Loss CO ₂	Per Cent. Loss.	Time in Hours.	Loss CO ₂	Per Cent. Loss.
$\frac{3}{4}$	·026	3·13	$\frac{3}{4}$	·0397	5·8	$\frac{3}{4}$	·0433	18·2
			$\frac{3}{4}$	·0467	7·56	$\frac{3}{4}$	·0463	19·3
			$\frac{3}{4}$	·0587	9·3	1	·0413	..
			1	·0637	10·1			

On the blast, therefore, 0·24 grm. strontium carbonate only loses 19·3 per cent. of CO₂ in three-quarters of an hour, while larger amounts of carbonate lose much less. This clearly disproves the statement to be found in Valentine, and previously referred to, that "strontium

carbonate heated in a platinum crucible over a gas blow-pipe is almost completely converted into oxide after about 20 minutes," and also the statement in Roscoe and Schorlemmer that "SrCO₃ when gently ignited loses all its CO₂, and is converted into strontia."

TABLE III.—BEHAVIOUR IN THE MUFFLE (TEMPERATURE ABOUT 1050° C., COPPER MELTING WITH DIFFICULTY).

I.			II.			III.			IV.		
1.26 Grm. Dry SrCO_3			.7272 Grm. Dry SrCO_3			.4035 Grm. SrCO_3			.2391 Grm. SrCO_3		
Time in Hours.	Loss of CO_2 in Grms.	Loss per Cent.	Time in Hours.	Loss of CO_2 in Grms.	Loss per Cent.	Time in Hours.	Loss of CO_2 in Grms.	Loss per Cent.	Time in Hours.	Loss of CO_2 in Grms.	Loss per Cent.
6	.349	27.7	2½	.202	27.8	6	.118	29.67	1½	.0588	24.5*
9	.559	29.25	7½	.215	29.6	9	.1265	29.64	6½	.0703	29.7
Per Cent. loss CO_2 = 29.25			29.6			29.64			29.7		

* The 0.2391 gram. had previously lost 19.3 per cent. over the blast.

In all these experiments the residue in the crucible had formed a cake which gave no effervescence with hydrochloric acid (the cake had been previously carefully moistened with a few drops of water) and therefore contained no appreciable amount of CO_2 .

An analysis of the residue in experiment II. showed that it contained 100.18 per cent. of strontia (estimated as carbonate), i.e., pure strontia is left on igniting strontium carbonate.

Summary:—

Loss over Bunsen,	Nil.
Loss over blast in 1 hour	{ From 19.1 per cent. on .6397 grm. SrCO_3 { To 19.3 per cent. on .2391 grm. SrCO_3 .
Loss in muffle,	{ From 29.25 per cent. on 1.26 grm. SrCO_3 { To 29.70 per cent. on .2391 grm. SrCO_3 .
CO_2 (found by analysis)	29.72 per cent.
CO_2 (theoretical)	29.83 per cent.

From these results it is evident that over the Bunsen there is absolutely no decomposition, whilst at a temperature of 1050° C. the strontium carbonate is slowly but completely decomposed into strontia and carbonic anhydride, the time required for complete decomposition varying with the mass of strontium carbonate taken.

The above work has been carried out in the laboratories of University College, Liverpool, and I have to thank Dr. Kohn for several suggestions with regard to it, and for the interest he took in it during its progress.

CONCENTRATED ESSENTIAL OILS OF LEMONS, LIMES, &c.

BY ARTHUR A. BARRITT.

IS bringing under your notice this evening the subject of concentrated essential oils, I think it will be well to pass in rapid review the state of our knowledge of essential oils, and more particularly its recent development.

As the subject is rather an extensive one I have limited myself to the oils of lemon and limes. These oils are of considerable commercial importance, and though our friends from Widnes and St. Helens whom I see here to-night may think the subject far less interesting than sulphuretted hydrogen and hydrochloric acid, and beneath their notice, yet the total value imported of the two oils together is very considerable.

Until quite recently it was laid down in our manuals of chemistry that many essential oils were identical in composition with oil of turpentine and chemically indistinguishable

from it. Gmelin, without attempting completeness, enumerates no fewer than 28 terpenes, all of which are represented as being compounds with the formula $\text{C}_{10}\text{H}_{16}$, yet differing from one another in some way not explained.

When the benzene nucleus theory came into vogue and the laws of isomerism began to be understood, these differences were attributed to isomerism or the position of the grouping in the molecule, but it was soon perceived that if this were so, the number of isomers was still strictly limited, and attempts were made to reduce Gmelin's 28 to more modest proportions.

One of the first of the modern school of chemists to investigate the subject was Dr. Tilden of Birmingham. He succeeded in proving the identity of several of the terpenes, and was the first to point out that in the cases of oils of lemon and orange the terpenes did not contain much flavour. Owing, however, to the high temperature employed in his method of fractionation, he unfortunately or fortunately seems to have come to wrong conclusions as to the properties of the high boiling portions of the oil.

Dr. Tilden was the first to point out that in the case of oil of lemon the terpene does not contain much flavour. My object to-night is to prove to you that it really contains none. Dr. Tilden says: "Of the various constituents of volatile oils the terpenes which are present in so many of them contribute less than any other to the peculiar odour of the oil."

In the case of oil of lemon he finds, in addition to terpenes, a compound ether $\text{C}_{10}\text{H}_{17}(\text{C}_2\text{H}_5\text{O})\text{O}$, which is decomposed by heat into a hydrocarbon ($\text{C}_{10}\text{H}_{16}$) and acetic acid. I have not been able to obtain any evidence of the presence of this body, and coupling this fact with the guarded words of Dr. Tilden, I have come to the conclusion that it does not exist.

About the same time—1877—79—that Dr. Tilden was at work, Dr. Gladstone and Mr. Kingzett made independent researches which confirmed Dr. Tilden's results as to the identity of the terpenes.

I have great pleasure in knowing that our countrymen led the way in the study of this important class of bodies, as at the present moment the classic research of Professor Wallach, Professor of Pharmacy at the University of Bonn, threatens to obscure entirely all that had previously been done.

Professor Wallach has devoted several years to the study of the terpenes, and his papers published in the "Annalen" relate the particulars of what may be described as a model research.

Without going into detail I may say that generally Professor Wallach has succeeded in classifying the terpenes and bringing them into some sort of order. At the same time a large number which were thought to be distinct from one another have been proved to be identical.

Thus—

Cineol, the terpene of oil of Worm seed.	
Cajeputene, " "	Cajeput.
Hesperidene, " "	Orange peel.
Citrene, one of the " "	Lemon peel.
Carvene, " "	Carraway.
Menthene, " "	Peppermint.

are all identical and may be termed limonene. This terpene is also present in oil of camphor, oil of dill seed, oil of erigeron, oil of pine needles. Naturally, it having been proved that the terpenes of lemon, caraway, and peppermint were identical, it at once became probable that in the same way that as the flavour of oil of caraway is due to carvol, peppermint to menthol and menthon, so oil of lemon would prove to owe its flavour to some quasi impurity of the terpene.

Chemists were not long in trying to isolate this, the characteristic constituent, and it is now possible to prepare it in an almost pure form. I am pleased to be able to lay before the meeting a sample of this body and also the body to which oil of limes owes its characteristic flavour. I have also samples of the terpenes from which these bodies have been separated.

If oil of lemon be distilled in a glass retort in the ordinary way over a gas burner or otherwise, and the distillation is not carried too far, the distillate will be found to be weaker than the original oil, whilst the residue in the retort is considerably stronger. This is the body, prepared in a more scientific way and completely freed from terpene, which I designate concentrated oil, and samples of which I now exhibit.

I term it concentrated oil because up to the present I cannot say with certainty what is its exact chemical composition. I hope to continue my investigations in this direction, and will meanwhile give you particulars of its properties.

Concentrated oil of lemon is neutral to litmus paper and has a pure lemon smell. It has a specific gravity of 901, never less than 900, at 15° C., and boils at 220° to 240° C., at which temperature it is partly decomposed.

Treated with bisulphite of soda it forms a magma and it is probably an aldehyde. With oxidising agents it yields a fatty acid. Warmed with metallic sodium it yields a brown mass.

A similar article to the one I am now showing was examined by Dr. Schweissinger, who published his results in the *Pharmaceutische Centralhalle*, and my results agree with his.

The terpene from which the concentrated oil has been separated retains a pleasant but weak odour, but is practically free from all flavour of lemon. The specific gravity is 850. It boils between 168° and 178°, and consists of pinene and limonene.

Concentrated oil of limes made from the fruit has not been previously prepared that I am aware of, though some work has been done in this direction by Mr. Francis Watt, chemist to the Montserrat Company. The oil which he examined and reported on to the Chemical Society of London was made from the leaves and young fruit of the lime fruit tree, *Linus limetta*. This is not a commercial article.

In this oil of lime leaves, Mr. Watt found a body boiling between 220° and 230° C., which he believes to be methyl-nonyl-ketone, $\text{CH}_3\text{COC}_9\text{H}_{19}$. This is possibly the same body which I am about to describe as concentrated oil of limes, made from the fruit.

Concentrated oil of limes as prepared by myself has a specific gravity of 920 to 923, is neutral to litmus paper and boils from 220° to 230° C. With bisulphite of soda it forms a magma. Warmed with metallic sodium it becomes very viscid, but not solid. With oxidising agents it forms a fatty acid.

The terpene from which the concentrated oil has been separated, contains a small quantity of a substance with a low boiling point, having a very objectionable smell, to which in a considerable degree the rankness of oil of limes is due. This is present in such small quantities that at present I have not been able to isolate it. The terpene when freed from this impurity has very similar properties to the terpene from oil of lemon. It retains a slight smell of limes, but is quite free from flavour. It boils at 176° to 180° C., and is probably nearly pure citrene.

Now as to the practical application.

Up to the present time the chief employment of these concentrated oils has been in the manufacture of liqueurs and syrups, and the improved flavour obtained by the absence

of the objectionable greasiness of the terpene makes them specially suitable for this purpose. A great point in their use is that they dissolve at once to a clear solution, and in spirit of a much lower strength than has to be employed when using crude oils. In this country, where the high duty on alcohol makes spirit such a very expensive article, this is a very important advantage.

In using them it is a good plan to dilute the oils to about the same strength as the oils from which they have been prepared with strong spirit, say, 56 per cent. over proof; 1 part to 29 parts of spirit. You then have a solution which can be used in old receipts without making any calculation. It is rather remarkable that this solution in strong spirit has but little smell, the odour being only developed when the solution is largely diluted with water. The same thing is noticed, but to a smaller extent, when ordinary oil of lemon is dissolved in spirit, but the terpene seems to aid the diffusibility of the odorous principle.

Having diluted the concentrated oil with strong spirit to the strength of the ordinary oils, they may be further diluted with weaker spirit or added to the bulk of the cordial or liqueur to be flavoured.

The following table represents in a convenient form the solubility of the concentrated oils in various strengths of spirit:—

Strength of Spirit.	Concentrated Oil of Lemon.	Concentrated Oil of Limes.
Rectified Spirit, sp. gr. 838	All proportions.	All proportions.
900	1 in 150	1 in 160
905	1 in 300	1 in 400
920	1 in 500	1 in 600
935	1 in 3,000	1 in 4,000

In confectionery uses have been found where the employment of concentrated oils is advantageous, and in articles where sugar or other dry powders are required to be flavoured with lemon, and where oxidation is very rapid, the use of concentrated oil is an improvement. As the boiling point is so much higher than that of the crude oils, it may be advantageous to use concentrated oils where high temperatures are employed in this department.

I do not doubt also that in perfumery concentrated oil of lemon will to a large extent displace the crude oil, owing, amongst other reasons, to the fact that it is quite free from the fixed fat and resin which is contained in ordinary oil.

How nasty this residue is, contaminated as it is with dirt from the hands of the none too cleanly Italian workmen who prepare the oil, you will have an opportunity of judging for yourselves from the sample on the table.

For perfumery I have to acknowledge one disadvantage, and that is, that in an alcoholic solution the odour is only developed when the spirit has entirely evaporated; when the perfume has evaporated on the handkerchief the purity of the odour becomes evident. I think that by using a small quantity of terpene in addition to the concentrated oil, this difficulty would be got over, and the advantages of being able to use a weak spirit retained.

An important point is: Do the concentrated oils keep? The answer is: Yes, much better than the crude oils. They should be carefully stored and the same precautions taken as are usual with valuable essences, and they keep well. It is quite impossible for them to become "turpentiney" as they contain no terpene, $\text{C}_{10}\text{H}_{16}$, whatever.

The deterioration of oil of lemon by keeping is due, in my opinion, to the production of nascent peroxide of hydrogen by the action of air and moisture on the limonene and pinene. This reaction, which has been so ably utilised by Mr. Kingzett in his Sanitas process, is highly objectionable in oil of lemon, rapidly destroying the aldehyde to which the flavour is due.

The best method therefore of preserving the flavouring principle of oil of lemon is to remove the terpene. It can then be kept, if excluded from the air, in the same way as any other aldehyde.

In conclusion, I have to thank the proprietors of the Lion Still chemical works for permission to read this paper and for the loan of the samples on the table.

DISCUSSION.

The CHAIRMAN invited discussion, remarking that although some members might consider the subject more suitable for a society of pharmaceutical chemists, yet it dealt with an important branch of chemical industry, and was well worth following up by experiments in the direction in which Mr. Barrett had worked.

Mr. M. CONWAY was obliged to the Chairman for an opportunity to speak on the matter under consideration. He had recently before him a small quantity of concentrated oil of lemon from a German firm, which, on careful examination, he found to be from 9 to 10 times stronger than the best oil of lemon, although it was said by the maker to be 30 times as strong, and at the time was fully 30 times denser. It was a very fine specimen possessing the aroma of the best oil in perfection, and soluble in a weaker alcohol than ordinary oil. For this reason and also on account of its better keeping properties, it was well adapted for the manufacture of perfumery, cordials, and mineral waters. He had not as yet given sufficient attention to the chemistry of these concentrated oils to enable him to discuss it on this occasion.

Dr. SYMES stated that he had had considerable experience in the treatment of essential oils, and referred to papers he had published on the subject. There was much in Mr. Barrett's paper that was in accordance with his own work, but he regretted that the author of the paper had given no attention to the refractive indices of the concentrated oils he had described.

In replying, Mr. BARRETT was sorry to tell Mr. Conway that the yield was considerably under 10 per cent. If so large a yield be obtained, the commercial possibilities would be much greater than they were. The treatment of a considerable bulk of oil during last season had resulted in a yield of a little over 3 per cent. The strength might therefore be fairly estimated at 30 times, but if purity of flavour were taken into account there could be no comparison between the two.

Dr. Symes was an old worker on the subject of essential oils, and had long advocated the use of a distilled oil of lemon which was superior for some purposes to the ordinary oil. In answer to his expression of regret that the refractive indices had not been given, he did not think the refractive index of materials like essential oils, consisting as they did of varying mixtures of bodies with different properties, was likely to be of any value. The same objection applied to the concentrated oils which had not been prepared up to the present with a constant boiling point. It was not his experience that concentrated oils, containing oxygen, would not deteriorate by further oxidation; and the surmise put forward in the paper that the chief constituent was an aldehyde would support this theory. The change, however, was less rapid with concentrated oils owing to the absence of the terpene, &c.

NOTES ON THE CONVERSION OF THE NITROGEN CONTAINED IN ACID SLUDGE OF OIL WORKS INTO AMMONIA.

BY T. J. REDWOOD.

SOME idea of the great importance of utilising the by-product "acid sludge" or "acid tar" of the Scotch oil works to better advantage than as fuel, can be obtained from the fact that from the estimated total production of about 37,000 tons of acid sludge per annum, a theoretical

yield of over 6,100 tons of sulphate of ammonia should be obtained; and this amount, at 11*l.* 5*s.* per ton, would realise 68,625*l.*, against (at 3*s.* 6*d.* per ton for acid sludge) 6,484*l.* as fuel.

It is therefore hoped that the publication of the results of experiments made by the author at the Addiewell works of Young's Company on the conversion of the nitrogen of the oily bases of this acid sludge into ammonia may be of material value to those who are in a position to carry on the experiments and make the process a commercial success.

The mixed tars resulting from the treatment of shale oils with sulphuric acid are of a thick treacly consistency, and contain about 50 per cent. of crude oily bases of the leucoline series, which, it was thought, might be decomposed by superheated steam, and the nitrogen thus set free made to combine with the hydrogen of the steam to form ammonia.

Numerous experiments on a miniature scale, after many failures, at last gave sufficiently encouraging results to justify the erection of a large experimental plant, a sketch of which is shown. The retort A was a cast-iron cylinder, 9 feet long by 6 inches internal diameter. The two cast-iron cylinders B and C, which were filled with pieces of coarsely broken brick, were used as contact chambers, and were so connected that by closing cock *a* and opening cock *b*, the gases passed through contact chamber B only. Whereas if cock *a* were closed and cock *b* opened, the gases passed through both contact chambers. D served as a condenser for the products of decomposition, which were separated in E, the gases passing on to the gas-holder F, while the water and neutral tars flowed out at *c*. G was the superheater, through which the steam passed before it entered the front end of the retort at *e*. H was the furnace connected with an underground flue.

Plan.

Back End Elevation.

Side Elevation.

Front End Elevation.

As it was evident that the acid sludge would soon destroy the iron retort, it was first neutralised with "lime waste" (*i.e.*, lime after it had been used to causticise recovered soda) and equal weights of acid sludge and lime waste were found to make a very satisfactory mixture to work with. In all the experiments the retort was charged with 10 lb. of this mixture at a time, and after the lapse of about 50 minutes the charge was drawn and a fresh one introduced.

In the first set of experiments, the gases were passed through one contact chamber only, and the apparatus was worked at a bright red heat. The average yield of products from 100 lb. of the above compound were:—

700 cub. ft. of gas.
25 galls. of ammonia water (yielding 385 grs. of sulphate per gallon).
2.45 lb. of neutral tar.

In the second set of experiments, the gases were passed through two contact chambers, and the apparatus was worked at a visible red heat. The average yields were:—

830 cub. ft. of gas.
18½ galls. of ammonia water (yielding 575 grs. of sulphate per gallon).
8.47 lb. of neutral tar.

The third set of experiments, using two contact chambers and employing a bright red heat, yielded the following results:—

816 cub. ft. of gas.
16½ galls. of ammonia water (yielding 670 grs. sulphate per gallon).
1.44 lb. of neutral tar.

The gas obtained was found to be sufficient to supply about one-half of the total heat required to run the apparatus.

The resulting neutral tar was found to be soluble in naphtha to the extent of about 65 per cent., but other characteristics will be referred to later.

The results of the above experiments when calculated on 100 lb. acid sludge are shown in Table I.

TABLE I.

In determining the yield of sulphate of ammonia, the titration test only was not relied upon, but the sulphate of ammonia was crystallised out, dried, and its strength determined.

Table I. shows plainly that both a high heat and ample contact surface are necessary for the complete decomposition of the neutral tars, and it also shows that double the contact surface with a lower heat is not so effective as a higher heat and half the contact surface, thus making it clear that a high heat is essential to the successful decomposition of the neutral tar. But when the heat is the same in both cases, the yield of neutral tar is halved by the doubling of the contact surface as is seen by comparing the results of the first and third sets of experiments.

As the sulphate of ammonia obtained from those experiments only represented about 16 per cent. of the total nitrogen contained in the acid sludge, and as an accurate knowledge of the distribution of the remaining 84 per cent. of nitrogen was indispensable for the successful conduct of future experiments, analyses of the various products were made in triplicate and the average results are shown in Table II.

Table III. shows the distribution of nitrogen calculated on acid sludge.

Nitrogen determined in acid sludge = 3.4980 per cent.

It is rather discouraging to note in Table III., that, on an average, 2.2242 parts of nitrogen (— about 63.5 per cent. of the total nitrogen contained in acid sludge) passes away in the gas without combining with the hydrogen of the steam to form ammonia, and that additional contact surface does not appear to promote in any way the chemical union of the gases. It was thought that the use of soda lime might tend to bring about the desired union, and the contact chambers were therefore filled with balls made of soda lime in place of the broken brick, but the results were unsatisfactory in the sense that the improvement was not sufficient to justify the additional expense. The particulars of the results of these last experiments have been unfortunately mislaid and therefore cannot be tabulated with the rest.

The specific gravity of the neutral tar from the above experiments was 1.129. The tar was wholly soluble in carbon disulphide; naphtha dissolved about 65 per cent., and when the naphtha solution was evaporated in the steam-bath, a black oily residue was left which had a specific gravity of 1.1 and yielded on distillation 65.92 per cent. of a thick dark tarry oil of 1.045 sp. gr. This distillate had a boiling point of 190° C., and when redistilled, 50 per cent. came over under 230° C. This redistillation could not be carried to dryness owing to the delivery tube becoming choked with a crystalline substance that on further examination proved to be an anthracene.

The portion of the neutral tar that was insoluble in naphtha was nearly as solid, but not so brittle, as pitch, and its specific gravity was 1.181. It was only slightly soluble in ether, and the ethereal solution on evaporation left a thick sticky residue. It was soluble in coal-tar benzol to the extent of about 60 per cent., and on evaporating the benzol, a nearly solid, black, sticky residue was left. It was wholly soluble in carbon disulphide. On distillation it yielded 15.3 per cent. of a black oily tar of 1.077 sp. gr.

For the past four years or so, two or three of the Scotch oil companies have been in the habit of recovering the acid from the acid sludge, and using the recovered acid for the manufacture of sulphate of ammonia. Recovered acid is of a very dark red colour, owing to its containing nearly the whole of the oily bases in solution, but as soon as it is neutralised with ammonia in the "cracker-boxes," those bases rise to the surface, and are now separated for use as fuel.

These oily bases could doubtlessly be obtained in quantity from any of the works where they are thus produced; and in the event of any of the members of this Society being inclined to carry on these experiments, they would find that experimenting with oily bases presents less difficulty than dealing with acid sludge, which latter, besides having to be neutralised with lime-waste, also has to be introduced into the retort by hand, whereas the retort could easily be fed with the bases by means of an injector worked by the superheated steam; a continuous and more satisfactory process of decomposition could thus be carried on.

As it is evident that a fire-clay retort, and contact chambers made of the same material, if maintained at a nearly white heat, will effect the complete decomposition of oily bases, the aim of future experiments should be the discovery of a contact substance capable of promoting the union of the free hydrogen and nitrogen, and sufficiently cheap to make the process of commercial value.

DISCUSSION.

The CHAIRMAN said that petroleum sludge had always been a difficulty with petroleum refiners, and if anything could be done to utilise its constituents to fuller advantage, it would be very advantageous to the refiners of petroleum and of shale oils. As far as he was able to judge Mr. Redwood's process, it did not appear to him that he had gone very far towards the solution of the problem.

Dr. Kohn said that he had written to Mr. Redwood asking him a few questions relative to his process, the answers to which he thought might be of interest to members.

In the first place he (Dr. Kohn) wished to know whether any analyses or determinations of the illuminating power of the gas obtained in the decomposition of the acid sludge had been made, and if so, whether the results confirmed the

large quantity of nitrogen which, according to Table III., occurred in the gas, as these results, which were taken by difference, had to account for the greater proportion of the total nitrogen?

Also had Mr. Redwood any direct evidence that the ammonia he obtained really was derived from the quinoline bases contained in the sludge, for one would hardly imagine that such a stable body as quinoline would be decomposed by superheated steam with the formation of ammonia?

Further, had the author made any detailed examination of the tar obtained in the decomposition, as this could throw much light on the actual nature of the process?

Mr. Redwood replied that no analyses of the gases resulting from the decomposition of the sludge were made, neither was the illuminating power of the gas determined photometrically, but close observation of the gas as it was burning in the furnace showed that it was highly luminous when the retort was newly charged, but gradually fell off in luminosity as the charge became spent, and during about 10 minutes before the charge was drawn only a blue flame was visible.

In regard to the decomposition of the leucoline bases by the superheated steam, having purified the crude bases by fractional distillations until products of the required constant boiling points were obtained, and having, in so doing, only met with a loss of about 15 per cent. (due to precipitation of coke and loss by adhesion of the bases to the bottles, &c.), it was evident that the loss shown to have taken place by decomposing the sludge in the retorts was due to the decomposition of the leucoline bases.

Considering the nature and sources of the acid sludge experimented with, he did not think it either possible or probable that the nitrogen obtained as ammonia was derived from any nitrogenous substance other than the leucoline bases.

Owing to pressure of other work, no examination of the nature of the distillates obtained from the distillation of the soluble and insoluble (in naphtha) tars resulting from the decomposition of the sludge were made, other than to determine that the crystalline substance that choked the delivery tube was anthracene.

Meeting held on Friday, 7th November 1890.

MR. IVAN LEVINSTEIN IN THE CHAIR.

SOME UNDEVELOPED INDUSTRIES.

BY PETER HART.

(ABSTRACT.)

MR. PETER HART gave a communication on "some undeveloped industries." He more especially referred to a species of cannel coal he had observed, which was to be found pretty plentifully in the neighbourhood of Worsley, near Manchester. On comparison with some Wigan cannel of similar appearance, by distillation and other tests, he found great resemblance to subsist between the cannels, both as to chemical character and also as to yield of products.

He suggested the utilisation of the cannel and shale for the production of oils, as practised in Scotland.

The other suggestion related to the possible propriety of the cultivation of the potato in Ireland not only for food, but also for the production of starch, farina, &c., so largely used by Lancashire calico printers and others.

Meeting held on Friday, 6th February 1891.

MR. IVAN LEVINSTEIN IN THE CHAIR.

THE PRACTICAL APPLICATION OF MAGNESIA CEMENT.

BY CARL OTTO WEBER, PH.D.

THE name of cement is applied to a certain class of chemical compounds, which, when in the form of a fine powder mixed with water, within a certain time form a solid homogeneous mass of stonelike appearance and great hardness. One class of these cements, which we may roughly term alumina-lime silicates, has developed into an industry of the highest importance producing millions of tons every year, although it is hardly 70 years since the beginning of the manufacture of these products on a large scale. The literature, scientific and technical, of this branch of chemical manufacturing is of extraordinary dimensions, which is, however, not very astonishing if we consider on the one hand the commercial importance of the article, on the other hand the very great complexity of this matter from a scientific point of view.

There exists however, besides the silicate of lime cements, a very great variety of other cements, some of which are used in workshops every day, but offering, neither commercially nor scientifically, much to interest us. As competitors with the alumina-lime silicates they are altogether out of the question. But there is a class of cements, the magnesia cements, which certainly are deserving of more attention than has been paid to them up to now, although I do not mean to say that they will ever rival ordinary cement in any considerable degree. But on the other hand there can be no doubt that these cements might easily find a considerable sale, so soon as the means are found to overcome certain unwelcome properties of them, which are the main impediment to their use.

The hydraulic properties of magnesium oxide have been discovered by Vical, the same man who may be considered the founder of the silicate of lime cement industry. Vical observed that freshly calcined magnesia hardens in contact with water, an observation which was confirmed by Macleod, but neither of the two seems to have followed up

this experiment any further. The matter rested for more than forty years, when Deville discovered that magnesia, obtained from chloride of magnesium by calcination, and carbonate of lime formed a cement, which under water sets to a mass in its outer appearance very much like marble, but considerably surpassing this material in hardness. Deville found that the hardness these cements attain depends largely upon the density of the magnesia used. Magnesia salts precipitated with alkalis yield a magnesia of great hardness, forming cements of a very poor quality, whereas the magnesia obtained from chloride of magnesium by calcination is of great density. To use Deville's method for the production of this cement on a commercial scale is out of the question for economical reasons. But considering the composition of Deville's cement, magnesia and carbonate of lime, it is not surprising that experiments have been made with a view to utilise dolomite, a natural magnesia-lime carbonate, for the manufacture of the product in question. If dolomite is heated to a temperature below red heat the carbonic acid of the magnesia carbonate, but not of the lime carbonate, is given off and the resulting product is Deville's cement. On further investigation of this matter, Craze Calvert found that the hydraulic properties of this cement increase with the proportion of magnesia which it contains, and that in strength and durability it is equal to a good average Portland cement. This standard, however, was subsequently contradicted by Erdmenger, who found these dolomite cements very much inferior to the average Portland cements.

The interest which this class of magnesia cement at one time attracted by-and-by subsided, and to-day the question of dolomite cements has sunk nearly into oblivion. If we take into consideration that dolomite cements could be profitably produced at about two-thirds of the price of Portland cements, it is obvious that their qualities must be of such an unsatisfactory kind as to render them unfit for successful competition with the silicate of lime cements.

At about the same time Deville made his researches on the magnesia-lime carbonate cements, Sorel discovered his magnesia cement, which he described as magnesium oxychloride. He produced it by forming a paste from a finely-ground magnesium oxide and a solution of magnesium chloride from 30 to 70 per cent. strong. This cement, which sets tolerably quickly, forming a very hard mass considerably harder than marble, gives extraordinary high figures in the crushing test, and possesses a tensile strength equal to nearly one ton per square inch, which is about three or four times the tensile strength of a good Portland cement. It has the further advantages of being fairly cheap, producing splendid concretes with as much as 10 times its own weight of indifferent materials, and having a beautiful white colour, so that it appears scarcely doubtful that if magnesia is going to win a place amongst the important cements, it will be in the form of Sorel's cement or some improvement thereon.

One of the most important items to be observed with magnesia cement is to use a magnesia of great density and as free as possible from carbonic acid. A few per cent. of carbonic acid absorbed by the burnt and powdered magnesia are sufficient to so considerably interfere with its action as to render it absolutely useless. The reason of this is, not that the magnesium carbonate formed, by its chemical properties, prevents the formation of a cement from the unchanged magnesia on the interaction of the solution of chloride of magnesium, but that the magnesium carbonate envelopes each particle with a film entirely indifferent against magnesium chloride, and although, in the centre of each such particle, the cementation takes place, that outside film of carbonate prevents the action from particle to particle, i.e., the agglomeration of the whole mass. A few days' exposure of the magnesia to the atmosphere are quite sufficient to make this substance unfit for use.

The magnesium chloride used for Sorel's cement is the ordinary product as it is used largely in textile industries. It is sold in casks, in which it forms a solid block of white colour and crystalline texture, containing about 48 per cent. of pure $MgCl_2$. Of this salt Sorel recommends the use of a solution from 30 to 70 per cent. strong, but I found the

results obtained are the more satisfactory the stronger the solutions used, and consequently I always use solutions about 80 per cent. strong.

If from magnesia and such an 80 per cent. solution of magnesium chloride a paste is formed, it sets within a few hours to a solid white mass, the hardness of which still increases for some days. The time of setting to a great extent depends upon the temperature and the moisture of the air at the time the experiment is made, high temperature and little moisture considerably accelerating the setting, whereas low temperature and moist atmosphere show a decidedly restraining influence.

The proportions of magnesia and magnesium chloride are of the greatest influence upon the qualities of the cement. I stated before that the cement produced was the harder the stronger the solution of magnesium chloride used, and this fact was already pointed out by Sorel himself. This might seem to imply that the hardness of this cement could be improved by increasing the proportion of magnesium chloride which enters in the composition. But this is not so. The fact is that in working the cement with an 80 per cent. solution of magnesium chloride, the strength of the cement decreases with increasing proportions of the chloride. The following series of experiments show this very clearly:—

No.	MgO	MgCl ₂ 6 aq. 80 per Cent. Sol.	Tensile Strength per Inch Square.
1*	10	6	1,748
2	10	8	1,300
3	10	10	1,150
4	10	12	1,028
5	10	14	860

* Besides the above proportion of magnesia and magnesium chloride 1 part of water was used, as without this the mixture appeared quite dry and had no plasticity.

This shows distinctly enough that a mere increase in the proportion of the magnesium chloride is detrimental to the cement, a fact which becomes still more prominent some time after the experiment, when first hair-cracks appear on No. 5 sample, which in due time develop into gaping fissures, owing to a swelling of the cement after setting. Samples 3 and 4 show the same phenomenon, only in a somewhat smaller degree, the amount of swelling being distinctly in proportion to the amount of magnesium chloride the samples contain. Samples 1 and 2 remain perfect for any length of time. Considering these facts, we must come to the conclusion that if the stronger chloride solution produces stronger cements than a weaker chloride solution, this not due to the relative increase in magnesium chloride, but to the decrease of the water of the solution. The correctness of this conclusion is borne out by another series of experiments. Sample No. 1 of the previous series showed the highest tensile strength and stability, and to find out the influence of water, or what comes to the same, of solutions of magnesium chloride less than 80 per cent. strong, I added to the various cement mixtures varying quantities of water:—

No.	MgO	MgCl ₂ 6 aq. 80 per Cent. Sol.	Water.	Tensile Strength per Inch Square.
6	10	7	0	1,468
7	10	6	1	1,784
8	10	6	2	780
9	10	6	3	700

Nos. 6 and 7 test were only made to check the correctness of the tests Nos. 1 to 5, and are in perfect accordance with them. Test No. 8 contains the same proportions of magnesia and magnesium chloride as test No. 7, but double the quantity

of water, and the result is a cement not half as strong as the latter; and still worse is No. 9 with 3 parts of water, notwithstanding the fact that the quantity of magnesium chloride is the same in each of the three samples. Sample No. 7 never shows any swelling or hair-cracks, but the samples No. 8 and No. 9 are in this respect as bad if not worse than samples No. 4 and No. 5.

These results show that the water of the solution of magnesium chloride plays a very important part in these cements, and acts not simply as a solvent. This is further shown by the fact that a solution of magnesium chloride in absolute alcohol does not form any cement with magnesia, no matter how long it is in contact with it, as long as the moisture of the air is excluded. Sorel considered his cement simply as an oxychloride of magnesium, but this compound very probably does not exist at all. All the samples I described contain a very considerable quantity of water, of which only a very small part is given off at 100° C.; and even at 200° C. not more than 70 per cent. of the total water the cement contains expelled. From this we have to conclude that the setting of Sorel's magnesia cement is one and the same process as the setting of the Portland cements, i.e., assimilation of water, this process of assimilation evidently being facilitated by the presence of magnesium chloride. According to this, we shall have to describe this cement as hydroxychloride of magnesium. Bender, to my knowledge, was the first to point this out. Bender evidently used a magnesium chloride solution containing about 50 per cent. MgCl₂ 6 aq., as the composition answered the formula MgCl₂ + 5 MgO + 17 H₂O. This cement lost 3 H₂O in the desiccator at ordinary temperature, 9 H₂O at 100° C., 11 H₂O at 180° C. On treating the cement with cold water, it lost MgCl₂, and the composition of the remainder answered the formula MgCl₂ + 9 MgO + 24 H₂O. Boiling water removes the magnesium chloride entirely, resulting in a cement of the formula 2 MgO, 3 H₂O, and Bender further adds that neither the treatment with cold nor with hot water has any destructive effect upon the agglomerated cement. My experiments do not corroborate this statement, nor is it in accordance with the results of the experiments made on a large scale with Sorel's cement. It is perfectly correct that water extracts MgCl₂ from the cement, which assimilates a proportionate amount of water, but this reaction invariably destroys the agglomeration of the cement; still more so if boiling water be used. This effect, produced by the action of water, makes Sorel's cement utterly useless for outdoor purposes, where it would be exposed to the influence of atmospheric moisture, and on that score failed all experiments on a large scale. The Union Stone Company in Boston, U.S.A., used Sorel's cement for the manufacture of artificial stones and emery wheels, and, as far as I am aware, the artificial stones were a failure. How the emery wheels turned out is not stated, but I am afraid the results were not very gratifying, as my own experience showed that emery wheels made from Sorel's cement are rather dangerous in use. They may for some time run right enough, and work extremely well, but they suddenly burst without any apparent cause. These very serious drawbacks are sufficient explanation that Sorel's cement, in spite of its cheap price and other advantages, is very little used.

If, instead of the magnesium chloride, a substance could be found which would form an insoluble compound with magnesia and at the same time have the same active properties with regard to the hydration of the magnesia, all these drawbacks could at once cease to exist and no doubt the magnesia cement would forthwith take its place as a cement of the first order, admirably adapted for the manufacture of artificial stones for building, ornamental, and a number of other purposes. Already Sorel hinted that magnesium chloride might be dispensed with and other compounds used instead, but at the same time he did not mention any compound better suited to the purpose than magnesium chloride. I experimented with chloride of potassium and chloride of sodium, both of which act in a similar way as the chloride of magnesium, but certainly with no better results. The chlorides of the alkaline earths do not answer at all, nor do any of the sulphates of the alkalis or alkaline earths. But there is a decided action by silicic acid, or such of the silicates which, being treated with hydrochloric acid,

produce gelatinous silicic acid. I experimented with powdered flint, infusorial earth, hydrated silicic acid, and anhydrous silicic acid, the two last-named produced from a solution of silicate of soda by addition of hydrochloric acid. The silicates I used were silicate of soda, silicate of magnesia, and silicate of lime. Powdered flint, as will be expected, showed extremely little, if any, action, although it had been most carefully incorporated to the magnesia; the cement it produced took a considerable time in setting, and was only moderately strong. Infusorial earth gave considerably better results, the cement setting very quickly and showing considerable hardness and strength. Hydro-silicic acid acted so suddenly that it was past the maximum of its action before it was properly mixed with the magnesia. Precipitated anhydrous silicic acid proved the best of the series, producing after 10 hours' setting a very hard and in every respect very strong cement of perfectly white colour. Silicate of soda forms with magnesia a paste which very soon hardens, without, however, producing a cement of any remarkable properties. The silicates of magnesia and lime behave very much like the soda silicate, but take a longer time to set than the latter. Of the whole series the precipitated anhydrous silicic acid showed to best effect, and was further proceeded with. A series of experiments was made to ascertain the best proportion of magnesia and silicic acid:—

No.	MgO	SiO ₂	Time for Setting, in Hours.	Tensile Strength per Inch Square.
10	100	5	32	211
11	100	7	24	313
12	100	10	15	780
13	100	15	14	1,300
14	100	22.5	12	992
15	100	30	10	510

To get reliable results it is necessary to incorporate the silicic acid with the magnesia as carefully as possible, otherwise the repetitions of one and the same test may nearly as widely differ in the figure representing the tensile strength, as any of two of the above tests differ from each other.

This shows that about 15 per cent. of silicic acid are required to give the best result as regards the strength of the cement. Test No. 14 was quicker in setting, but considerably weaker. But even No. 15, the strongest of the series, remains considerably behind the figures we found for the magnesium chloride cements; but on the other hand, these cements made with silicic acid are perfectly indifferent against water, cold or hot, and under no circumstances begin to swell after setting. But a difficulty in the practical use of these cements would be their very great liability to become inert so very soon after exposure to the atmosphere. Two or three hours' exposure I found quite sufficient to nearly annihilate the hydraulic properties of this cement mixture. This is certainly a very serious drawback, as in practical use it would mean a great deal of waste; but it can be overcome simply by mixing the siliceo-magnesia cement with a solution of magnesium chloride instead of water. The cement thus formed sets in about 10 hours, and forms an extremely hard mass, which in strength even surpasses Sorel's cement without sharing the unwelcome properties of the latter. Water takes up magnesium chloride from this cement as from Sorel's, but no expansion is noticeable. Treatment with cold water is quite sufficient to extract all the magnesium chloride, the place of which in the cement is taken by water hydrating the magnesia.

The admixture of silicic acid with Sorel's magnesia cement makes the latter closely related to the hydraulic mortars as well as the Portland and Roman cement, as the formation of a hydraulic magnesium silicate in that mixture is beyond doubt. On treatment of this new cement, after setting, with hydrochloric acid, it slowly decomposes. The whole of the magnesia and about 30 per cent. of the total

silicic acid contained in such a cement are in solution, the rest of the silicic acid appearing in the gelatinous state. The best proportions for the preparation of this new cement I found to be—

100 magnesia.

15 silicic acid.

90 magnesium chloride solution, 80 per cent.

This cement is of a tensile strength equal to 1,788 lb. per inch square, the most important part being the mixing of the magnesia and silicic acid, which must be done as carefully as possible. Absorption of carbonic acid previous to use to the extent of about 2 per cent. has scarcely any effect upon it, a larger proportion acts in precisely the same manner as in the other magnesia cements, and must be avoided.

The practical application of a magnesia cement free from the defects pointed out above will be very great indeed, owing to its cheapness, remarkably fine colour and great agglomerating capacity, many times surpassing that of Portland cement. As far as my personal experience goes magnesia cement is a material of the first order for the manufacture of artificial stones for ordinary building and ornamental purposes, for the manufacture of emery wheels, and for the production of artificial lithographic stones. Only in the first of these applications named it can be said to enter into competition with Portland cement, the other applications being altogether beyond the scope of the latter. Whether magnesia cement will ever be capable of competing with Portland cement in general concreting work and constructions under water I am hardly able to give an opinion yet, but it may interest you to hear that I employed it successfully for the construction of engine beds, the results also from an economical point of view being highly satisfactory.

The materials which can be utilised for the manufacture of artificial stones from magnesia cement are preferably such containing silica or silicates. Sand, crushed granite, porphyry, glass, Yorkshire and Cheshire sandstones, and the like answering very well. The quantity of cement to be used depends very little on the chemical nature of the filling-up material, but is very considerably influenced by the coarser or finer granulation of the materials used. The strengths such mixtures attain is, however, quite independent of the degree of granulation, as under all circumstances we are able to produce from any of the above filling-up materials with magnesia cement a composition very much stronger than the cement itself. This seems a very remarkable fact, and a few examples may serve to illustrate it. I used in the following series of experiments emery simply because this material is readily obtainable crushed to a number of standard sizes, the grains varying in size from $\frac{1}{4}$ of an inch (emery No. 6) to $\frac{1}{2500}$ of an inch (emery No. 200 or emery flour). The samples were always tested one week after they had been made, as it was found that after this time they gain in four months about 5 per cent. only in strength.

This series clearly shows the remarkable fact above referred to, *i.e.*, that mixtures of magnesia cement and indifferent mineral materials produce compositions at least as strong as the cement itself, and eventually twice as strong. But this result is subject to certain conditions, the most important of which is, that the cement mixture used must be such as to allow each particle of the filling-up material to be got perfectly coated with it, after which the mixture must remain of a rather moist, not dry and sticky, appearance. There are, of course, two ways of arriving at this end, the one being to use a rather thin flowing cement mixture to start with, or to use a larger quantity of a dryer cement mixture. Of these two ways, I found the first to give the better result. The strongest cement mixture I produced is No. 1, *viz.*, 10 parts of magnesia and 6 of magnesium chloride solution: these proportions produce a very dry mixture, and you will see that in combination with emery it yields a composition very much inferior in tensile strength to a similar combination made with No. 3 cement, although the latter in its pure state is very much weaker than No. 1. Experiments Nos. 16, 17, and 18 all contain the same cement mixture, but you see how the strength is increased simply by using larger proportions of it, that is

making the combined mixture of cement and emery moister. The importance of this point is still better illustrated by using the finer emery, 24 or 36. You will notice that the 20 per cent. compositions, Nos. 16, 20, and 23, show a great falling off in strength corresponding to the finer granulation of the emery, but in every instance the 40 per cent. compositions, Nos. 18, 22, and 25, show the same strength. By using more than 40 per cent. of the cement mixture no further increase in strength is obtained; on the contrary it begins to decrease, and at about 80 per cent. the combined mixtures show the same strength as the corresponding pure cement. Emery flour, however, forms the exception of the rule, as it reaches its maximum strength with 60 per cent. cement. It never attains the strength we could obtain with coarser material, but on the other hand we reach the minimum strength, that is the strength of the pure cement only in using equal parts of cement and emery flour.

Cement No. 1 forming an exceedingly stiff paste, it is quite clear that, although it is about the strongest magnesia cement which can be produced, it will never give satisfactory results in combination with indifferent materials. Of course it might appear that its excessive stickiness by addition of water could be so reduced as to give it the required fluidity, but if you look at experiment No. 28, which represents the strongest compound I could obtain under these conditions, you will see that, although it is much stronger than the corresponding experiment No. 19, still it remains considerably behind the strength of the pure cement. This might still be accounted for by deficient fluidity, and no doubt it is; but by adding more water, as in experiment No. 29, you see that the result shows the contrary of an improvement. This is evidently due to the detrimental influence of the water, shown by the experiments 8 and 9, and also by No. 30, which otherwise corresponds to No. 18.

No.	MgO	MgCl ₂ 6H ₂ O per Cent. Sol.	Water.	Emery 16.	Emery 24.	Emery 36.	Emery Flour.	Tensile Strength, Lb. per Inch Square.
16	10	10	..	100	1,100
17	15	15	..	100	1,428
18	20	20	..	100	2,236
19	10	6	..	100	868
20	10	10	100	901

30	20	20	2	100	1,360

Considering the great strength of compounds of magnesia cement, it will appear that it is very well adapted for the manufacture of emery wheels, and indeed it has been used for this purpose for some time; but such an emery wheel is scarcely safe enough in use for reasons I pointed out before. If, however, to Soré's magnesia cement the silica magnesia cement be substituted, the wheels produced are of remarkable toughness, and perhaps as safe as the emery wheels considered the safest of all, namely, those made with india rubber as cohesive matter. The proportion of cement in the magnesia emery wheels ought not to be less than 20 per cent. of the emery; it never exceeds 50 per cent. Of a somewhat similar nature is the use of this cement for the manufacture of mill-stones. The face of these stones can be made from emery with a backing of crushed flint. Such mill-stones are, in hardness, lasting quality, and general efficiency very much superior to natural stones, especially for the grinding of very hard material. For corn grinding they are not so well adapted, though they are used very extensively for the shelling of rice.

The future of the magnesia cement seems, however, to lie in its application for the manufacture of artificial building stones, as very small percentages of the cement are required to form remarkably strong stones. Nearly any mineral material can be used for this purpose, and especially good results can be obtained with mixtures of sand and not too coarse pebble or gravel. The stones may be coloured, or given an ornamental face backed by ordinary material; in this way stones are obtained which at very moderate cost resemble in appearance polished marble or granite. The most important question with regard to these stones is of course whether they will resist the influence of the atmosphere as well as a good natural building stone. As far as artificial

stones from Soré cement are concerned, this question must be answered in the negative; but stones made from the silica magnesia cement withstood the influence of the atmosphere for over 12 months without showing the slightest sign of deterioration. Amongst the specimens I brought here to-night you will find some which have been exposed for a considerable period without in any way looking the worse for it.

A few experiments which I made with a view to produce artificial lithographic stones proved very successful, in so far as the stone I obtained behaved in practical use in every respect like the natural lithographic stones from the Bavarian quarries, but it did not yield the same number of impressions as the latter. This difficulty, however, I consider not very difficult to overcome, as it merely seems to be a question of the absorbing qualities of the stone. The artificial production of these stones would be a matter of no small commercial importance, as up to now the trade in lithographic stones is monopolised by the Bavarian quarry owners.

DISCUSSION.

Mr. J. CARTER BELL asked if the author was aware of recent statements widely circulated in the continental and English papers, with regard to the great danger of magnesia in Portland cement. If magnesia cement possesses the excellent properties which the author claims for it, why should its presence be objectionable in Portland cement?

Dr. WEBER, in reply to several questions raised in the discussion, said with regard to Mr. Hart's remarks he did not think magnesia cement would enter into competition with ordinary cements, as in the first instance it was a

little more expensive than Portland cement, and it applied to quite a different class of uses, such as the manufacture of building stones, emery wheels, ornamental stones, and similar articles for which ordinary cement was rather unsuitable. He had seen the article referred to by Mr. Carter Bell in some of the English technical papers on the subject of magnesia in cement, but this had no bearing on the magnesia cement in question. The detrimental effect of magnesia on Portland cement was due to the fact that the hydration of the Portland cement had come to a standstill when the hydration of the magnesia was taking place, and as this was accompanied by a swelling of the magnesia the result was a destruction of the hardened Portland cement. With regard to the composition of the magnesia cement, the prevailing idea was that magnesia cement was oxychloride of magnesium. This, however, was not the case, as pointed out in the paper. The presence of magnesium chloride in the cement after setting appears to be only accidental, and the composition of the set cement was simply that of hydroxide magnesia. With regard to the action of sea-water on ordinary cement, he found it to have a very detrimental influence, whereas magnesia cement was not affected by it. After the extraction by water of the magnesium chloride from the cement, the cement showed if anything a slight increase in strength, and, further, for the amount of magnesium chloride extracted from the cement, a proportionate amount of water is assimilated.

THE COMPOSITION AND DIGESTIBILITY OF GREEN FODDER AND OF ENSILAGE, WITH NOTES UPON ARTIFICIAL DIGESTION AS AN ANALYTICAL METHOD.

BY DAVID WILSON, JUN., M.A., F.C.S., AND P. R. HARPER.

THROUGH the kindness of Mr. Speir, Newton Farm, Cambuslang, we received, in September 1889, nine samples of clover, representing the produce of separate plots, and one sample of ryegrass. These plots had all borne the same rotation of crops, and farmyard manure had been applied to none of them since 1875, but each had been dressed annually with a mixture made up on Ville's principle of omitting the constituents in turn from a complete artificial manure. The produce of each plot was also kept distinct in the silo at Newton, and samples of the ensilage from each sent us.

After weighing, the samples were air-dried, ground in a mill to a fine powder, and bottled for analysis. In the air-dried samples, moisture was determined by heating at 110° C. in a current of dried air; total nitrogen by a soda-lime combustion; and the albuminoid nitrogen by the copper hydroxide method, using, however, twice the amount of that precipitant recommended by Stützer. The fibre was obtained by Hlenneberg and Stohmann's method. The numbers in Table I. are the means of at least two, and in some cases of four and six, determinations. Duplicate results are given for total nitrogen and albuminoid nitrogen to show the limit of error.

It is evident that the composition of clover does not vary greatly with manure. In the above table the plots are arranged in the order of weight of crop, and it will be seen generally, as the crop increases the fibre and ash in the dry matter increase slightly, but the percentage of albuminoids decreases.

The composition of clover varies greatly with the stage of maturity at which it is cut, as is seen from Table II. The results of which these are the average were obtained by us from clovers grown at Carbeth.

That the composition also varies with the soil and climate is evident from the average albuminoids in 13 samples cut in bloom at Carbeth being lower than any of the nine samples grown at Newton, all cut at the blooming stage. As formerly shown by one of us,* the influence of manures on the composition of crops can generally be traced to their action in increasing succulence and reducing maturity. Such action is always most evident with soluble nitrogenous manures, and it was therefore to be expected that a leguminous crop like clover, which is not dependent on such a supply, nor materially increased thereby, would show very little difference in composition with varying manurial treatment. Differences of climate, soil, and subsoil, as affecting the conditions of maturity in clover to a greater extent than differences of manure, have also a much greater effect on its quality. Weight of produce, therefore, is the only end that need be considered in manuring clover, and the feeding value of the crop per ton will depend on the stage of development at which it is cut.

The ensilage made from these plots had been 90 days in the silo. It was scarcely of the best quality, being rather soft and sour. The pressure applied was 1 cwt. per square foot area of the silo, but owing apparently to the succulence of the clover the temperature did not rise above 125° F. Mr. Speir's experience is that 130° F. is necessary as a minimum to secure sweet silage.

The composition of the clover silage from the different plots varies in the same direction as the clover before ensilage. The sample of ryegrass was stemmy, somewhat yellow at the bottom, and appeared partially dried when received. The ryegrass silage, on the other hand, being compact, had retained its moisture during transference.

The ash or mineral matter is not liable to change in the silo except so far as its soluble portion may be removed in the juice expressed by the pressure. The produce of the

experimental plots was in the middle of the silo. Assuming therefore that the small amount of soluble ash lost in expressed juice would be balanced by that gained, as 100 lb. of the dry matter of the clover contained on the average 9.50 lb. ash, the average amount of the various constituents in the ensilage corresponding with this amount of ash, and therefore with 100 lb. of clover put into the silo may be calculated thus:—

	True Albuminoids.	Non- Albuminoid Nitrogen × 6.25.	Carbohydrates, &c. (by difference).	Fibre.	Ash.	Total.	Total Nitrogen.
100 lb. dry matter of clovers, average .	16.47	3.91	46.33	23.79	9.50	100.00	3.261
Ditto, when taken out of silo.....	15.74	4.04	33.94	27.35	9.50	90.57	3.164

The loss, due to fermentation in the silo, on these samples seems to have fallen almost entirely on the carbohydrates. Roughly, of 46 lb. of "carbohydrates" put into the silo only 34 lb. were taken out. The greater part of this has been entirely lost, but a small quantity, which was when put into the silo soluble in dilute acid and alkali, has become insoluble during the fermentation, and goes to increase the "fibre." The loss of nitrogenous food material has not been great in the ensilage process as conducted at Newton. There appears to have been a slight loss of total nitrogen, but this may be due to dissociation of some organic salts of ammonia—such as ammonia acetate and lactate—during the preparatory air-drying of the samples of ensilage. The process of ensilage, so far as already investigated, has frequently been accompanied by a change of the albuminoids of the fodder into non-albuminoid forms, some of which, ammonia for example, are of no feeding value, and the others (amides and amido-acids), are at least inferior to albuminoids in this respect. It will be seen, however, that the amount of non-albuminoid nitrogen is but very little higher in the ensilage from Newton than in the clover before it was put into the silo. Though, therefore, considerable decrease in feeding value often does occur by the degrading of the albuminoids in the silo, it is evident that this loss is not inseparable from ensilage, but is dependent on the substance ensiled, and on the conditions of the process.

Our main object in publishing these analyses is to point out another kind of deterioration to which albuminoids seem

to be subject in the ensilage process, viz., decrease in their digestibility. Though much work has been done in Germany and America in determining the digestibility of albuminoids in different feeding stuffs, both by experiments upon living animals, and more recently by the artificial method, the experiments with ensilage in this direction have been few, and we are not aware of any upon silage made from clover or ryegrass. In experiments with living animals the quantity of each constituent supplied in the food and not recovered in the solid excrement is taken as the digested portion of that constituent; and the numbers so obtained have generally been entered in the tables of digestibility without correction for biliary compounds and mucus in the solid excrement. The method of artificial digestion as originally proposed by Stützer has been found by Ladd* and others, to give results agreeing well with these tables. We have examined the feeding stuffs used from time to time at Carbeth by this pepsin method. In Table IV, the average of the results obtained are compared with the maximum, minimum, and average results of experiments made in Germany upon living animals. Where no name is given these are on the authority of Julius Kühn (Mentzel and v. Lengerke's Landw. Kalender), and the others from the 1888 edition of Emil Wolff's Landwirtschaftliche Fütterungslehre.

These results show that artificial digestion with pepsin affords a good criterion of the *relative* digestibility of the albuminoids in different feeding stuffs; and if a method could be found to measure as nearly the digestibility of the non-nitrogenous constituents, we believe it would revolutionise the analysis of fodders. We are at present engaged upon experiments in this direction. When practical men tell us that the market price of feeding stuffs is a better index of feeding value than chemical analysis it is time to revise our methods.

Stützer prepared his pepsin solution directly from the inner membrane of a pig's stomach, but more constant and satisfactory results can be obtained by using "scale pepsin," as it can be preserved in the dry condition, and so a fresh solution made up for each digestion experiment. The results tabulated were got as follows: 2 grms. of substance, in the finest state of division, were repeatedly triturated with cold water in a mortar, the clear liquid being poured through a filter. When the substance was thoroughly reduced to paste, it was transferred to the filter and washed till the washings came through free from colour. The substance on the filter was then transferred to a bottle by means of 100 cc. of water and 1 cc. of 33 per cent. hydrochloric acid, and 0.1 gm. of scale pepsin added. The bottles thus prepared were loosely stoppered and immersed in a bath of water kept at 40° C. for 12 hours, with occasional shaking. The contents were then filtered, washed till free from acid, dried, and ignited with soda-lime. The result in nitrogen multiplied by 6.25 gives the indigestible albuminoids as usually tabulated.

The above method, however, cannot give the absolute digestibility of feeding stuffs, for in the animal system the albuminoids that have not been rendered soluble by gastric digestion are acted upon by the pancreatic juice in the intestines; and similarly it has been found artificially that a solution of pancreas dissolves a considerable proportion of the albuminoids which had resisted the action of pepsin. Accordingly Stützer* now recommends that the residue from the pepsin digestion—his earlier process—should be further treated with an alkaline solution of pancreas. As has been shown, however, the pepsin alone gives for many foods at

least as high results as the experiments on animals. It follows that either the successive actions of the artificial pepsin and pancreas solutions are more powerful in dissolving albuminoids than that of the digestive fluids in the animal, or that some considerable error is involved in the ordinary method of determining the digestibility of albuminoids by experiments on living animals. It was known, indeed, that the solid excrement of animals contains varying quantities of bile which has escaped resorption, and of mucus, and that the nitrogen of these was erroneously reckoned as indigestible albumen of the food; but, under the impression that the error thereby caused would be small, it was generally neglected in stating the results of digestion experiments. Further work has proved that this assumption was not justified, and Stützer,† Pieffer,‡ Jordan,§ and others, indeed all who have recently compared the artificial and natural methods of digestion on the same foods, agree in concluding from their investigations that the artificial pepsin-pancreas method gives the same result as digestion experiments with animals provided that the true correction be made in the latter for the nitrogen in the solid excrement due to biliary compounds and mucus. They differ to some extent as to the best method of estimating this correction, but, accepting their unanimous conclusion, the artificial method has the advantage not only of being much easier of execution, but also of eliminating the coefficient of the individual, which is a factor in all results got from living animals.

The pancreas solution was prepared by Stützer from the sweet-breeds of oxen. Having tried this process, we prefer to use the prepared extract of pancreas sold as "pancreatine." The results given in Table V. were obtained as follows:—The residues from the pepsin digestion, conducted as before described, after being washed free from acid, and before drying, were transferred back to the bottles by means of 100 cc. of water. To each bottle 0.15 gm. Savory and Moore's pancreatine and 0.3 gm. sodic carbonate were added, and the whole heated for 12 hours at 40° C., as in the pepsin digestion; the residue filtered, washed, dried, and ignited with soda-lime. The nitrogen so obtained multiplied by 6.25 gives the indigestible albuminoids.

Mean } Clovers }	20.25	16.57	7.11	3.06	64.81	57.14	84.82	81.48	21.84	17.38	13.43	7.47	38.45	22.56	65.45	56.44
Rye-grass	12.10	8.46	4.01	1.84	66.87	52.60	84.79	78.25	9.96	7.08	6.04	3.24	39.37	14.69	67.47	54.24

Taking the average of these eight samples of clover, they contain 16.57 per cent. of true albuminoids, and of this 9.46 per cent. are digested with pepsin alone, but after passing through the fermentation of the silo only 3.95 per cent. are soluble in the pepsin solution. So notable was this difference, that additional experiments were made increasing the hydrochloric acid at regular intervals until the digestive solution contained 1 per cent. HCl, but this modification, adopted by several experiment stations in America, did not alter to an appreciable extent the results obtained. The re-digestion with pancreatic has dissolved about half of the albuminoids which resisted the action of pepsin both in the clover and in the ensilage. The difference in the digestibility is therefore not so noticeable with pepsin-pancreas digestion as with pepsin alone. It may be inferred, however, as the result of both methods, considering the former as a relative and the latter as our nearest approach to an absolute measure of digestibility, that the process of ensilage, as conducted at Newton upon these samples of clover and ryegrass, has to a very marked extent reduced the digestibility of the albuminoids they contain, and the value of the fodder proportionately.

We cannot chemically formulate this change. While the individual albuminoids—the pure nutrients—may be taken as wholly digestible, the group that goes under that name in fodder analyses, consisting of all the nitrogenous substances insoluble in water, as well as those that are precipitated by copper hydroxide, are admittedly only partially so; and the heat and acidity developed in the silo may affect the proportions in this complex group. Or, as it has been shown that the ensilage process in this case has increased the so-called “fibre,” it may have so acted upon the walls of the individual cell as to render the contents less easily acted upon by the juices of the alimentary canal.

There are thus two ways in which the fermentation of the silo may practically destroy albuminoids; first, by changing them into amides and other less valuable compounds, as shown in samples of ensilage examined by Prof. Kitch, Mr. Clifford Richardson, Mr. W. H. Jordan, Sir J. Lawes, and Dr. Gilbert and others; and, secondly, as shown here by rendering them indigestible. The extent of the loss in both

cases will depend on the nature of the substance ensiled, and on the conditions of the process. One way or the other there will be loss of those feeding constituents of which our farms produce too little, and which are the most expensive to buy in. It would seem advisable, therefore, in practice to reduce the risk of serious loss by pasturing, or making into hay-crops like clover and other leguminosae, and to confine ensilage to those crops which are poorer in albuminoids. It is in providing succulent winter food, and as a substitute for roots, which contain but little true albuminoids, that ensilage has its place and value.

DISCUSSION.

Dr. G. G. HENDERSON said they were much indebted to Mr. Wilson for giving them another instance how the application of chemical knowledge to agriculture might be of the greatest possible value. Could Mr. Wilson inform them how certain of the “albuminoids” were rendered indigestible in the process of silage. One could easily enough understand how they were changed into amides and other compounds, but he wished to know if the change by which these albuminoids were rendered indigestible had been studied, and, if so, what was the explanation of the fact.

Mr. D. WILSON said he was not in a position to give a definite answer to Dr. Henderson's question.

*Meeting held in the Philosophical Institution, Edinburgh,
on Tuesday, February 3rd, 1891.*

DR. J. B. READMAN IN THE CHAIR.

THE NITROGEN OF CRUDE PETROLEUMS AND PARAFFIN OILS.

BY GEORGE HELLRY.

In a former paper I have shown (J. III., 216) that the ordinary crude oil distillate from average Scotch oil shale contains from $\frac{1}{2}$ to $\frac{1}{4}$ of the nitrogen of the original shale. This oil contains from 1·16 per cent. to 1·45 per cent. of nitrogen in the form of basic tars which readily combine with, and are almost completely removed by, sulphuric acid of sp. gr. 1·220. These basic tars are the principal impurity of crude shale oil.

When crude shale oil is re-distilled it leaves a residue of pitchy coke which contains about 3 per cent. of nitrogen.

When the basic tars which have been separated by sulphuric acid are neutralised and distilled, the percentage of nitrogen in the various fractions is pretty constant, varying from 3·24 per cent. to 3·51 per cent., and the undistilled residue contains 4 per cent. of nitrogen. Therefore in the distillation of the basic tars as in the distillation of the crude oil, the nitrogen tends to concentrate in the undistilled residue.

In the same paper the following statement occurs:—

"In 'Watt's Dictionary' (I. 426) there is a table of analyses of certain natural bitumens, which are found to contain from 1 to 2·3 per cent. of nitrogen, thus indicating their probable organic origin. In this connexion it is interesting to note that while all crude oils or naphthas, artificially prepared by the destructive distillation of carbonaceous deposits, contain nitrogen in the form of alkaloidal tars, the natural American petroleum does not contain any nitrogen. This statement is based on the results of the examination of many shiploads of crude petroleum residuum which have passed through the refinery at Oakbank works during the last 12 years. If, therefore, these petroleum products have been produced from organic deposits by a process of subterranean distillation, what has become of the organic nitrogen?"

In view of the possible value of this observation as a contribution to the study of the origin of natural petroleum, I decided to carefully re-examine American petroleum and to extend the examination so as to include various other natural petroleum products. The results of this examination, which was made some years ago, are now published for the first time.

AMERICAN PETROLEUM.

When crude petroleum is distilled the refiner takes off as distillate about 90 per cent., leaving in the still about 10 per cent. of residue, which contains the higher boiling oils and paraffin and most of the tarry impurities. This residue is commercially known as "residuum."

Unlike crude shale oil, petroleum residuum gives no separation of basic tar with dilute acids, but concentrated sulphuric acid separates a thick pitchy tar. This tar is quite free from the smell of pyridine bases which is so characteristic of shale tar.

All of the nitrogen determinations which follow were made by soda-lime in extra long tubes heated very slowly to give ample time for the complete decomposition of the basic tar vapours by red-hot soda-lime. If in any case sensible quantities of oily or tarry matter appeared in the condensation bulb, the experiment was rejected as likely to give too low a result. As the actual quantity of ammonia obtained was very small it was absorbed in HCl and weighed as platinum double chloride.

Analyses were made of the residuum, of the pitchy coke left by it on distillation and of the tar separated from the

distillate by concentrated sulphuric acid. The following are the results:—

	Per Cent. Nitrogen.
Residuum.....	0·080
Coke ($\frac{1}{2}$ of residuum)	0·375
Tar ($\frac{1}{10}$ of residuum).....	0·710

The nitrogen found in the coke and tar is equal to 0·078 per cent. on the residuum or practically the whole of the nitrogen originally present.

The residuum is about one-tenth of the original petroleum, so that the amount of nitrogen found is equal to 0·008 per cent. on the original oil. A part of the nitrogen of the original petroleum may have passed over with the 90 per cent. distillate, but there cannot have been much, as that distillate is almost a refined burning oil and does not contain more than a small percentage of tar.

I have now to correct the statement in my former paper as quoted above, as it is now found that crude American petroleum contains at least 0·008 per cent. of nitrogen.

RUSSIAN CRUDE PETROLEUM.

Mr. Beverton Redwood having kindly sent me samples of Baku petroleum and its residuum or "Astutki," these were analysed and gave the following results:—

	Per Cent. Nitrogen.
Baku crude petroleum.....	0·05
Baku crude petroleum residuum...	0·05

Only a small part of the Baku crude is distilled off as burning oil, the larger part remaining as residuum, so that there is less apparent concentration of nitrogen in this case.

Galician Ozokerite.

A sample of crude earth wax or ozokerite from Galicia was analysed and gave 0·188 per cent. of nitrogen.

Scotch Petroleum or Ozokerite.

In 1885, in sinking a pit at Midealder from the "Broxburn" seam of shale to the "Dunnet" seam (see diagram in Mr. Stewart's paper, J. Vol. VIII. 100) a seam of very hard crystalline limestone was cut through, in the crevices of which small quantities of a greenish-brown, translucent, semi-solid wax or ozokerite were found. From its situation, not far from a trap dyke which had disturbed the shale seams, it seemed most probable that this ozokerite was a distillate from one of the shale seams which had condensed in the cracks and crevices of the limestone. In view of its probable origin it was thought that a determination of its nitrogen would be of interest, and the following result was obtained:—

	Per Cent. Nitrogen.
Scotch petroleum or ozokerite	0·296

Only a small quantity of this petroleum could be obtained, so that it was not possible to assay it for oil and paraffin products, but its appearance suggested that it was a tolerably pure product rich in solid paraffin.

The "Broxburn petroleum" described and analysed by Mr. D. R. Stewart (J. VI. 128), must be very similar to the petroleum found in the Midealder pit, and, from their situation with reference to the shale seams, it is probable that both were produced from the same seams. Mr. Stewart's experiments showed that this petroleum only suffered a loss of about 16 per cent. on refining, as compared with 27 per cent. lost by the best artificially distilled oil, and as most of this loss is due to basic tars, it may be taken as a rough index of the quantities of these tars, and therefore of the nitrogen in the oils.

Comparing the natural and the artificial distillates from the same shale seam at Midealder we have:—

	Per Cent. Nitrogen.
Natural petroleum contains	0·296
Artificial (retort-distilled)	1·160

The natural distillation in the earth evidently produces a much purer distillate, containing a much smaller percentage of nitrogen and basic tars; so that the smallness of the percentage of nitrogen in American and Russian crude petroleum cannot be held to exclude them from classification as distillates from organic remains.

The actual percentage of nitrogen in any distillate must always be largely determined by the nature of the organic remains from which it was derived. We should never expect a coal, chiefly derived from the woolly parts of large trees, to give a distillate containing as large a percentage of basic tars and nitrogen as we should from a shale derived from animal remains or from the seeds and more highly nitrogenous parts of plants.

From the results recorded in this, and in my former paper, it seems probable that an explanation of the much smaller percentage of nitrogen in natural as compared with artificial oils is to be found in the tendency of the nitrogenous bodies to concentrate in the residues of distillation. It is easy to picture a condition of subterranean distillation in which the oil is distilled out of the shale by the heat from intruding lava, and condenses in the immediate neighbourhood among the earthy particles, only to be again distilled and driven to a fresh condensing place when sufficient heat reaches it by conduction. A few such distillations and condensations would reduce the nitrogen of the final distillate to a mere fraction of its former amount. Any of the nitrogen which might be converted into ammonia or volatile bases would, of course, disappear, leaving no trace behind.

TABLE OF NITROGEN DETERMINATIONS.

	Nitrogen per Cent.
Scotch shale oil from retorts	1'160
Scotch petroleum or ozokerite	0'296
American petroleum residuum	0'080
Baku petroleum	0'050
Baku petroleum residuum	0'050
Galician ozokerite	0'188
Scotch basic tar	3'900
American residuum tar	0'710
Scotch crude still coke	3'200
American crude still coke	0'375

DISCUSSION.

The CHAIRMAN asked if Mr. Beilby would state the amount of nitrogen usually found in the Broxburn shale, and the proportions of that nitrogen recovered as ammonia, that is, how much went into the tar and the oil?

Dr. G. G. HENDERSON said it appeared from Mr. Beilby's results that in the distillation of shale, &c., there was a tendency towards accumulation of nitrogen in the residues of the distillation, and therefore that the smallness of the quantity of nitrogen found in petroleum could be accounted for by assuming that that substance was a product of some natural process of distillation of organic matter. He did not know whether any positive proof could be led in support of this supposition—whether, for example, there were any traces in oil-bearing districts of natural processes, such as irruption of volcanic rocks, by which distillation of organic matter could be brought about—but at any rate Mr. Beilby's results seemed to go against the view that petroleum and similar substances were formed by the action of steam on carbides of the metals in the interior of the earth at very high temperatures. He would be glad to know Mr. Beilby's opinion on this subject.

Mr. G. BEILBY, referring to Dr. Henderson's remarks, said they had certain facts before them which might lead themselves more or less to one or other theory of the origin of petroleum.

First.—The retort distillates from fossil deposits in peat, coal, or oil shale, contain nitrogen, generally as alkaloidal bases.

Second.—A number of petroleum which have been examined contain nitrogen probably in the form of bases, as it is all removable from the distillate by sulphuric acid.

Third.—The experiments on the concentration of nitrogen in the residues of distillation offer a possible answer to the question: Why do the natural petroleum contain so much less nitrogen than the retort distillates?

Fourth.—In the case of the Scotch petroleum or ozokerite, its character and its situation with reference to the seams of shale make it highly probable that it is a natural distillate from the shale.

In answer to Dr. Readman's question, he stated that in the retort distillation of an ordinary Scotch shale one-fifth to a quarter of its nitrogen appeared in the oil distillate.

Mr. W. Hume, philosophical instrument maker, Edinburgh, exhibited and explained a portable form of Mr. John Aitken's pocket dust counter, which he had prepared for that gentleman. He explained its details by means of lantern illustrations, pointing out its importance and value in determining the amount of dust particles present in the air.

Journal and Patent* Literature.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

The Production and Utilisation of Artificial Cold.
G. Richard. Bull. Soc. d'Encouragement l'Industrie
Nationale, 1889, 629—661 and 749—773.

This elaborate memoir was compiled by the author at the request of the organising committee of the *Congress Internationale de Mécanique appliquée*. The whole subject of the machinery employed for the production of artificial cold is exhaustively treated. The applications are less fully dealt with except in the case of the manufacture of ice. No less than 246 patents are referred to in the memoir. In addition the following sources of information have been largely drawn upon.

Ledoux.—*Theorie de Machines à froid* (*Annales des Mines*, July—August 1878).

Haton de la Goupillière.—*Cours de Machines.*

Armengaud.—*Étude sur la production mécanique de froid*, 1874.

Lightfoot.—*Machines for Producing Cold Air* (Inst. of Mech. Engineers, January 1881; see also this Journal, 1886, 133—142).

J. Coleman.—*Refrigerating Machinery* (Inst. of Civil Engineers, February 14, 1882; see also this Journal, 1884, 357—366 and 1887, 253—258).

Gottlieb Behrend.—*Eis und Kalteerzeugungs Maschinen*.
Also the work of Lezé on ice machines, papers by Kirk
and by Kilbourn and other original matter.

Formerly the means principally employed for producing cold were :—

1. Saline solution.
2. Latent heat of evaporation.

The first is entirely restricted to domestic use.

The second principle is applied in the well-known apparatus of Carré (Eng. Pat. 4164 of 1876), in which the water to be frozen is cooled by evaporation in vacuo, the

* Any of these specifications may be obtained by post, by remitting the cost price, *plus* postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d.	½d.
Above 8d., and not exceeding 1s. 6d.	1d.
" 1s. 6d., " " 2s. 4d.	1½d.
" 2s. 4d., " " 3s. 4d.	2d.

vapour being absorbed by sulphuric acid. Various patents were taken out in connexion with this method which was applied on the large scale. Difficulties with the pumps, and the necessity for continual renewal of the acid prevented their success. The employment of sulphuric acid, moreover, was a bar to their application for domestic use. The use of sulphuric acid was avoided in Atkinson's machine (Eng. Pat. 16,547 of 1886) in which the vapour was condensed, but at the expense of a loss of efficiency.

In the machinery used at the present time the source of cold is in every case the *latent heat of expansion*, aided in one of the two important classes of machines by the *latent heat of evaporation*.

There are two principal classes of refrigerating machines (1) in which the expanding body is the air; (2) in which the expanding body is the vapour from a condensable gas, generally ammonia, but sometimes sulphur dioxide or carbonic acid.

This second class may be sub-divided according as to whether—

(a) The vapour is liquefied by pressure.

(b) The vapour is liquefied by absorption in a solvent.

The variety of machines in class (2) is very large. By far the most important, however, are those in which the working substance is ammonia and the means of liquefaction is *compression*. The bulk of the memoir is occupied with descriptions of different types of air machines and ammonia compression machines. The former enjoy at present a practical monopoly of the installations on board ship, being used for the preservation of meat. In the opinion of Diesel this monopoly is simply due to the fact that hitherto a type of ammonia machine suited to ship-board has been wanting. Such a type has been designed by Linde, for the White Star Line. In opposition to the views of Diesel, Richard points out, what is indeed sufficiently evident, that a principal objection to the employment of ammonia or other condensed-vapour machines on board ship is that if any accident occurs during the voyage, there is no means of replacing the working substance. Again, change of climate scarcely affects the working conditions of the air machines, which is far from being the case with ammonia machines. On the other hand, for permanent installations on land, the machines working with a liquefied gas (generally ammonia) are to be preferred. They are less cumbersome than air machines, owing to the greater specific heat per unit volume of the working substance, and they need no arrangement for the removal of moisture.

Theory of Air Machines.

In order that the air may be cooled, it is caused to do work by expansion in a cylinder of the steam-engine which drives the machine (see description of Fig. 1). The capacity of the expansion cylinder is defined by the formula—

$$\frac{c}{d} = r - 1 = n \cdot p \cdot d$$

where c = volume of compression cylinder, r = expansion, n = ratio (1.41) of the two specific heats of air. The refrigerating air machine being exactly the inverse of a hot-air engine, its maximum efficiency depends on the ratio—

$$\frac{T_2}{T_1 - T_2}$$

T_1 and T_2 being the absolute temperatures of the compression cylinder and of the freezing chamber. The efficiency, therefore, diminishes as the difference of temperature is greater, or, in other words, as the expansion of the air is greater. At the same time, with a smaller difference of temperature, the frigorific power of the machine diminishes. An expansion of 2.5 is found to be about the best value. The efficiency rarely exceeds 80 per cent. The highest result that one can expect to attain with a pressure of four atmospheres is 1,000 negative calories per horsepower per hour of the compression cylinder, and 25 calories per cubic metre of air passing through the machine. During compression the air should describe, as nearly as possible, an isothermal. The cooling is effected by cold water circulating round the compression cylinder, sometimes aided by an injection of water. The principle of the regenerator has been applied, in the case of machines which do not work in a closed cycle, by employing in the compression cylinder air drawn from the refrigerating chamber (Windhausen, Eng. Pat. 669 of 1869, and Bell-Coleman). Kirk's regenerator (Eng. Pat. 1218 of 1862), although ingenious and correct in principle, has not come into general use.

The principal parts of an air machine are:—

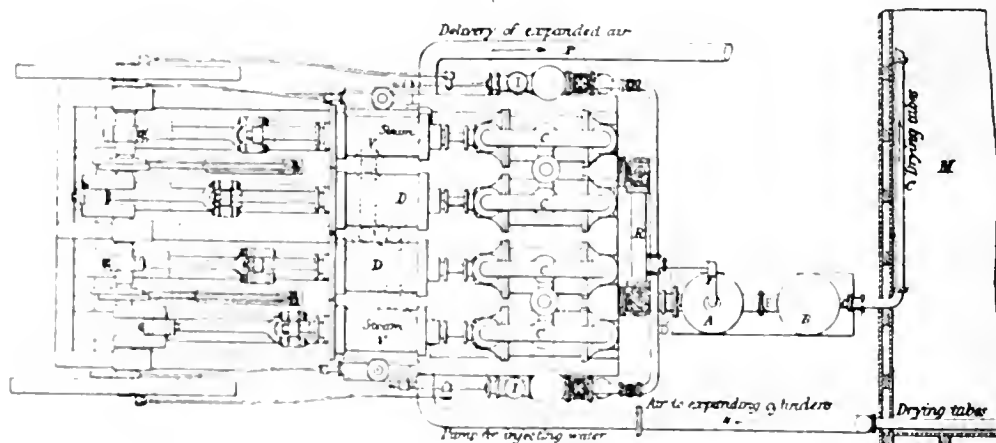

1. The compression cylinder.
2. The cooling and drying chamber.
3. The expansion cylinder.
4. The freezing chamber.

For the compression cylinder double action is almost universal on board ship. On land, single action is frequently used. Valves of various types are mentioned, those of Mathews (Eng. Pat. 5648 of 1886) being figured and more fully described.

Previous to 1877 the deposition of snow during the expansion and consequent cooling of the air had proved an insurmountable difficulty in the practical working of these machines. Bell and Coleman first showed how the aqueous vapour contained in the air can be satisfactorily removed. This they did by a further cooling of the air after compression and before expansion. In this way it is deposited not in the solid but in the liquid form, and, in Bell-Coleman's machine, is drawn off by means of sloping pipes furnished with bottom taps. The pipes may be placed in the freezing chamber, or cold air may be brought from this chamber to the pipes.

The details of the machine are shown in Figs. 1, 2, and 3. These machines are largely used on the Australian shipping lines.

Fig. 1.

The two steam cylinders V work four compression cylinders C¹ and two expansion cylinders D. The pumps I injecting water at the ends of the compression cylinders effect the first cooling. The compressed air from C¹ passes through R and D' to the cooler A. This is a tower with horizontal perforated plates through which trickles water from F. The air enters at the bottom and passes out at the top by E, cooled and saturated with moisture into the drying tower B. This contains perforated plates on which a large part of the moisture deposits. From the bottom of B the air passes into the sloping tubes c c in the freezing chamber

M. The moisture is here completely removed as already described, and the air passes by it to the expansion cylinders D D from which it is delivered by I to the freezing chamber M.

In Hall and Lightfoot's machines (Figs. 4, 5, and 6), the second cooling is effected in a small expander followed by a net-work drying arrangement (Inst. Mech. Eng. Jan. 4, 1881). This method is more compact than Bell and Coleman's. Hall and Lightfoot's machines are largely used in the foreign meat trade.

Fig. 2.

Fig. 3.

COMPRESSION CYLINDER.

The double action compression cylinder C delivers the air at an absolute pressure of about 4.5 kilos. to the tubular cooler B, where it begins its expansion and is cooled to about 0° C. Thence it passes over the network G (Fig. 6) of the intermediate drying arrangement D (Fig. 4), where it deposits the greater part of its moisture before passing to the back of the expansion cylinder E. The steam cylinder A is coupled to the cylinder E in such a manner that the motion of the piston of A is assisted by the expansion of the air. Velocity, 63 revolutions per minute.

The Paul Giffard machine of 1877 (Eng. Pat. 627 of 1873, 2064 of 1875, and 3108 of 1877) has again a different drying arrangement. This is said not to work so well; nevertheless, these machines are in extensive use as, e.g., on the P. and O. vessels.

Where a special cooling and drying arrangement is not employed a *snow bar* is necessary. In this the air as it leaves the expansion cylinder deposits its snow or ice on a surface which has preferably the form of a network (Hargreaves and Inglis, Eng. Pat. 1747 of 1878).

Machines Worked by a Gas Liquefied by Compression.

In these machines the cycle is always a closed one. As has been already stated, ammonia prepared by heating commercial ammonia liquor, is the substance generally used. The theory of this class of machines is not known with the same exactness as that of air machines. The law, however, applies to both equally that the efficiency increases as the difference of temperature is less between the compression cylinder and the freezing chamber. The efficiency is sensibly independent of the nature of the working substance. It depends largely on working the compression with as little superheating of the vapour as possible. This necessitates an abundant circulation of cold water round the compression cylinder, and only a moderate piston velocity.

The following are the most important points in which the construction of these machines differs from that of the air machines. (1.) Absence of arrangement for condensing moisture. (2.) Absence of special cylinder of expansion, the expansion being generally effected simply by opening a cock placed near the freezing chamber, between this and the compression cylinder. In carbonic acid machines, however, an expansion cylinder is sometimes employed (Windhausen, Eng. Pat. 2549 of 1888; this Journal, 1889, 269). (3.) Special provisions on account of greater pressure. The forms of valve are different, and great attention has to be paid to the stuffing-boxes, &c. in order to avoid leakage. The pistons also are of special forms. (4.) Additional arrangements for keeping the compression cylinder cool. (5.) The vessel in which the working substance is liquefied.

Valves.—These are generally of iron or steel; conical and furnished with a spring. Their movement is in almost all cases regulated by the pressure of the gas itself. It is important that they should work without shock, and that they should be readily accessible. Among the devices by which these points are secured may be mentioned those of Fixary and of Wood (Eng. Pat. 16,558 of 1884, and 14,606 of 1886, *vide Engineer*, February 4, 1887).

Stuffing-Box.—Much difficulty has been experienced in preventing leakage, especially with double-action compression cylinders. According to M. Richard this difficulty is completely overcome by the employment of Fixary's *joint piteux*. The device consists in causing some of the cold expanded ammonia to circulate round the oil of the stuffing-

box so as partially to freeze it. In this semi-solid or highly viscous material the piston works without leakage and with little friction. The compression cylinders in which this joint is employed are shown in Fig. 7.

Cold, expanded ammonia is brought by *c* and circulates in *b b*, round the oil *a a*, through which the piston rod works. The gas then passes by *d* to the suction.

Pistons.—In most vertical machines there is a layer of oil above the piston which is said to do away with the clearance, and which at the same time lubricates the piston. In Lavargne's compression cylinder a deep layer of oil is used and the piston is so constructed that the greater part escapes during the ascent between the packing of the piston and the sides of the cylinder. The remainder passes

Fig. 4.

GENERAL PLAN OF THE MACHINE.

Fig. 5.

EXPANSION CYLINDER.

Fig. 6.

DRYING ARRANGEMENT.

through the delivery valves and serves for lubrication of other parts of the machine. This piston works tight and with reduced friction, and Richard's contention that it completely does away with the clearance appears to be correct. The oil is kept constantly renewed. Were this not done its action would be interfered with owing to its becoming saturated with ammonia. This supply of oil helps also in the cooling of the compression cylinder as does Fixary's joint piston.

Cooling of the Compression Cylinder.—It is possible to do this effectually (where ammonia is the working substance) simply by a circulation of water. This fact is proved by the indicator diagrams which have been taken with Linde's machines. Additional means of cooling are, however, frequently employed. The injection of a spray of the liquefied gas is used by Wood (Eng. Pat. 5798 of 1882 and 9547 of 1886) and also by Puplett (Eng. Pat. 12,513 of 1884). Raydt employs a hollow piston cooled inside by a current of water.

Liquefaction.—The liquefaction is effected in tubes kept cool either by being surrounded by water or by being exposed to a jet of water. In Lavargne's machines there is in addition an auxiliary condenser cooled by the return of the expanding gas. Some such arrangement is necessary in the case of machines in which the working substance is carbonic acid (*vide* Raydt's liquefying arrangement, Eng. Pat. 1352 of 1880). Considerable ingenuity has been exercised in securing the joints of the liquefying tubes. A figure of Kilbourn's arrangement is given in the memoir.

The refrigerating arrangement is of a form depending on the use to which the machine is put. Most frequently it is of a form which may be regarded as the inverse of the compression cylinder. The gas is expanded in tubes surrounded by an agitated liquid (generally brine), which is cooled by the gas.

The ammonia machines are manufactured by numerous firms. The position they hold is largely due to Linde,

whose machines are in extensive use in Germany and elsewhere.

The Puplett machine (horizontal type) is also described (this Journal, 1889, 970, and 1890, 166).

Machines working with Liquefiable Gases other than Ammonia.

We may confine ourselves to the mention of those working with either sulphur dioxide or carbon dioxide. The former gas has less frigorific power than ammonia, and has the further disadvantage that the least trace of moisture getting in results in the rapid corrosion of the machinery.

Fig. 7.

FIXARY'S JOINT PÂTEUX APPLIED TO SINGLE ACTION VERTICAL COMPRESSION CYLINDERS.

Machines employing carbon dioxide have a special interest. The frigorific power of the substance is much greater than

that of ammonia, and by some authorities carbon dioxide is looked upon as the refrigerating agent of the future. It is certain that carbon dioxide machines even now have a practical value, and are capable of further development. Arguments are not wanting, on the other hand, in favour of the view that with the actual conditions under which engineers work in respect of strength of material and atmospheric temperature, ammonia will always be preferable to carbon dioxide. The question would be capable of a definite solution by the equations of thermodynamics, but that unfortunately the necessary knowledge of the physical constants of the gases is wanting. M. Richard advocates the establishment of a technical laboratory devoted to the investigation of problems such as this connected with the industry of refrigeration. In default of the information which such an institution might afford, the matter will probably have to be decided by trial on the large scale.

Pietet employs a mixture of carbon dioxide and sulphur dioxide. It appears premature as yet to pronounce on the likelihood of the success of this experiment.

Absorption Machines.

There is a class of machines in which ammonia gas is absorbed by water, instead of being condensed by pressure. The first absorption machines to be used on the industrial scale were those of Carré, now made in France by MM. Rouart. Similar machines are also produced by MM. Imbert. A special feature of absorption machines is the rectifying apparatus, for condensing and removing the aqueous vapour with which the ammonia is mixed. Among the most efficient of these arrangements are those of Reece and F. Stanley (Eng. Pat. 2891 of 1870, and 3907 of 1875) and of Pontifex and Wood (Eng. Pat. 15,064 of 1887). Notwithstanding the ingenuity expended upon them, absorption machines do not meet with general favour.

Applications of Refrigeration.

Of the numerous applications of refrigeration, only three are dealt with in the memoir, viz. :—

1. Manufacture of ice.
2. Cooling of buildings (theatres, &c.).
3. Preservation of meat.

Of these, only the first is treated at all fully.

In the manufacture of ice the chief difficulties are connected with obtaining the material transparent and sufficiently pure for consumption. This is best effected by distillation under high pressure, followed by ebullition under atmospheric pressure. The distilled water, freed from air, then passes through tubes surrounded by a liquid, such as brine, cooled by the circulation of expanded gas to moulds also surrounded by brine, and here the water is frozen. Fig 8 shows the arrangement adopted by Linde (Eng. Pat. 16,270 of 1886; see also this Journal, 1890, 481 and 594).

Fig. 8.

MANUFACTURE OF TRANSPARENT ICE BY LINDE'S PROCESS.

The steam from the high-pressure boiler A condenses in the worm *b* of the low-pressure boiler B. The steam from B works the driving engine G and escapes by *m* to a condenser. The hot water formed by the condensation of steam in *b* passes into the receiver C, where, being under atmospheric pressure only, it enters into ebullition, the dissolved air escaping, together with a little steam, by *g*. The water (pure and free from air) passes by *h* through the cooler D, and by *g*, H, and *r* to the moulds, where it is frozen. The boiler A is fed by the pump E, which draws water through *i* and delivers it by the worm *p*, where it is warmed by the hot water from C.

In M. de Stoppani's machine (Eng. Pat. 3363 of 1887; *vide Revue Industr.* Nov. 16, 1889) the steam from the driving engine is used for making the ice. Where this is done, special arrangements are necessary for removing grease. The cost of manufacture of transparent ice is stated at from 6 fr. to 10 fr. per ton with good machinery.

Cooling of Buildings (as Theatres).

(*Vide* Sir W. Thomson "On the Heating and Cooling of Buildings by Means of Currents of Air." *Proc. Phil. Soc. of Glasgow*, Dec. 1852.)

This application of refrigeration is still in its infancy. The problem is, however, of considerable importance, and its importance will increase as European civilisation gains ground in tropical and semi-tropical countries.

Two methods have been tried: first, the direct method of disseminating small volumes of intensely cold air produced by machines in which air is the working substance. When ammonia machines are used, another principle is generally adopted, viz., that of cooling brine in tanks by the circulation of the gas through worms immersed in these tanks. The cold brine is then made to circulate through pipes in a manner similar to that employed for warming buildings by hot water. In connexion with this branch of the refrigerating industry should be cited Fixary's process (Eng. Pat. 3793 of 1887).

Preservation of Meat.

The meat chambers are best kept at a temperature of about 0° C., and not lower, since if the meat be actually frozen, it is liable to putrefaction when allowed to acquire the ordinary temperature. The cold air is distributed through the freezing chambers by means of wooden pipes furnished with *snow boxes* to collect the hoar frost formed from the moisture given off by the meat.

Although the air machines have a practical monopoly of the installations on board ship, the meat is often preserved at the *dépôts* by ammonia machines (e.g. at the Victoria Docks, London, by one of Chambers' machines).

In the United States special railway waggons are employed for the transport of refrigerated meat. These are ice waggons with non-conducting walls and a ventilating arrangement (*vide* Lavoigne and Pontzen, *les Chemins de fer en Amérique*, 2, 83).—W. W. H. G.

The Amsterdam Exhibition of Appliances for the Prevention of Accidents in Factories. Van Vliet. *Chem. Ind.* 1890, 13, 455—457.

In 1886 the Dutch House of Deputies appointed a committee to inquire into the state of the working classes of Holland.

The outcome of this was the above-named exhibition, which comprised the following objects of importance for chemical factories:—To guard against danger in *spirit distilleries*, the still must be hermetically connected with the worm. The head of the still supports a globe by which the aqueous and alcoholic vapours are condensed, and a system of tubes is so arranged that a whistling noise is heard as soon as air mixes with these vapours. By this device leakage is easily discovered. In *varnish factories* the boilers are placed on wheels, that they may be quickly removed from the fire in case of danger. The *carbogs used for acids* are protected with iron bands, and various arrangements for safely emptying them by means of air pumps, suction pipes, &c., are recommended.

Special attention was given to the subject of *ventilation*. Various systems were recommended for factories, e.g., Blackman's, Wing's, and the Victoria ventilator.

Designs for *workmen's dwellings*, bathing establishments, &c., were numerous, and it was calculated that in Holland, lodgings consisting of two rooms, alcove and kitchen, can be provided for 3s. per week, and yet yield a profit of 4 per cent. to the building companies. The charge for a bath is equally cheap, viz. 1½d.

Ladders of wire rope, coiled in boxes, placed between the windows of factories, would minimise, if not prevent, all danger from fire. Very numerous were the contrivances to prevent accidents from machinery, automatic lubricators being especially prominent.—H. S.

Accidents in Prussian Factories. *Chem. Ind.* 1890, 13, 468—470.

MANY and different reasons are stated as the causes of accidents, viz.: It is statistically proved that a great many accidents happen on Mondays. This is owing, in the majority of cases, to the notorious alcoholic excesses of the working classes on Sundays.—Moreover, men in charge of boilers and all kinds of machinery are especially liable to various kinds of accidents, and it is proposed to introduce a certain examination for these people, and to admit only trustworthy and able men. This rule should be strictly observed, and, if necessary, even legally enforced.

The danger from fire has, of late, been greatly reduced, by using only non-inflammable materials, such as stone, iron, &c., in the building of factories, by having fire-engines and hydrants in constant readiness and a good supply of water in all parts of the buildings. Highly to be recommended in this respect is the arrangement recently introduced into textile factories, viz., of erecting buildings consisting of ground floor and basement only. It is hardly necessary to remark that the employment of the electric light greatly diminishes the danger from fire. As a whole, great improvements are noticeable of late in the arrangements for the prevention of accidents from fire.

Ladders attached to machines, and employed chiefly in lubricating certain parts of them, are very often unsafe, and in conjunction with the bad conditions of the lifts, lead to many accidents which might easily be prevented.

Carbon bisulphide seems to be especially dangerous, as men who are engaged in filling carbogs or bottles with this liquid may easily be poisoned. The dust of potassium chlorate is also a dangerous substance, on account of its inflammability. Those occupied in the manufacture of potassium chlorate should always be compelled to change their clothes before leaving the factory. Dyeing establishments should generally be better ventilated, as the various vapours often so fill the rooms as to make it almost impossible to see from one end to the other, thereby greatly increasing the probability of accidents. Glasses for the protection of the eyes are absolutely necessary in factories where acid or caustic liquids are used, and many accidents have happened from neglecting this simple precaution. Although great improvement for the prevention of accidents can be recorded, yet it must not be forgotten that the extreme carelessness and negligence of the workpeople themselves are the causes of the greatest and most constant danger and no remedy has yet been found against this.

—H. S.

PATENTS.

Improvements in Apparatus for Treating Fabrics, Paper, and other Materials with Gases, Steam, or Hot Air. E. Remy, Mülhausen, Germany. Eng. Pat. 20,905, December 30, 1889. 8d.

See under VI., page 135.

Improvements in Apparatus for the Evaporation of Liquids. W. Wild, London. Eng. Pat. 398, January 9, 1890. 11d.

THE object of this invention is to ensure more perfect concentration of the liquid under treatment.

An outer chamber has fixed centrally within it an inner chamber, preferably of a cylindrical form, for heating the liquid before its entry into an evaporating coil, and is connected at its upper part to a suitable reservoir. In the space between the two chambers, and surrounding the inner one is a coil, formed of any suitable metal, but copper is preferred, tapering from its upper extremity, and increasing in diameter towards the lower end. The upper end of the coil is connected with the inner chamber by a small pipe, the flow of the liquid being regulated by a tap or valve. The lower end of the coil terminates at any convenient part of the outer chamber, and is connected by a pipe with a separating box, inside which are placed, vertically, groups of pipes, the groups being separated by vertical screens extending partly across the box, so as to allow the liquid to circulate among the pipes in an irregular manner, and thus separate the liquid from the vapour. The heating medium injected into the outer chamber circulates round the coil, and after giving up more or less of its heat, passes out by a pipe. The liquid under treatment is supplied from a reservoir, and enters at the top of the inner chamber under pressure, and rising in a pipe, reaches the coil, whence it passes into the separating chamber, from which the concentrated liquid is removed by a pump. To obtain more perfect concentration, several of these machines may be combined.

—E. S.

Improvements in Purifying Water, and in Apparatus therefor. E. Devonshire, London. Eng. Pat. 480, January 10, 1890. 4d.

IN this invention, fragments of flint, limestone, or basic slag are substituted for iron or other materials usually employed, and are placed, either separately or together, in a rotating cylinder provided with hollow trunnions, through which the water flows. Shelves are placed in the cylinder, by which the material is constantly lifted and allowed to fall through the water. The apparatus employed is such as is described in Eng. Pat. 5496 of 1883, 12,256 of 1884, and 10,706 of 1889.—E. S.

Improvements in Apparatus for Separating Iron from Bones or other Substances. F. Christy, Chelmsford, and J. H. Carter, London. Eng. Pat. 530, January 11, 1890. 8d.

THIS invention is for the separation of iron pieces, such as nuts, bolts, &c., from bones and other substances to prevent damage to the grinding machinery. A cylinder of iron studded with a large number of electro-magnets set radially, and the outer ends of which are of alternate polarity, is used. The magnets are so commutated that during one half of a revolution they are active, and during the other half passive. The feeder on to the cylinder is kept continually shaken, so as to cause the iron to work itself under the other material by gravity, and so come more directly on to the magnets. When dealing with a material of nearly the same density as iron, the mechanical separation is assisted by placing powerful electro-magnets on the under side of the feeder. The material to be treated is fed on to the top of the cylinder and carried forward as it revolves. The non-magnetic material falls off at the side and the iron is carried half-way round and dropped into a box beneath the cylinder. When the apparatus is combined

with a grinding machine so that the non-magnetic material delivered from it passes into the feed-hole of the grinding machine, it serves as an automatic feed, and saves the labour of feeding by hand.—B. H.

Improvements in Filter-Presses. J. Brock and T. Minton, Widnes. Eng. Pat. 606, January 13, 1890. 8d.

THE improvements are intended to facilitate the opening and closing of cylindrical filter-presses such as are described in Eng. Pat. 2127 of 1887 (this Journal, 1888, 313), and mainly consist in supporting the cylinder on bearings at its ends, instead of on supports underneath, thus allowing of a clear space for emptying; and also in the mode by which the various parts are connected.—E. S.

Improvements in Filters for the Purification of Water and other Liquids. A. Smith, London. Eng. Pat. 828, January 16, 1890. 6d.

A CYLINDRICAL case is provided at each or one end with a water-tight cover. In each cover is a central hole through which a pipe with screwed ends, and having "fly-nuts," passes. The pipe being longer than the case, forms both the outlet and the inlet. It has several perforations in its length, and beneath one or more of the upper ones, near the inlet end, a plug is placed so that the liquid to be filtered must flow into the interior of the case, the remaining holes acting as outlets for the filtered liquid. The pipe is either filled with the filtering medium or is surrounded by it. This construction affords ready access to the interior for either cleansing or renewing the filtering medium.—E. S.

An Improved Receptacle or Apparatus for Containing Material for Absorbing Moisture or Humidity. R. A. Kemp, London. Eng. Pat. 1242, January 23, 1890. 8d.

THIS invention relates to an improved box for containing deliquescent salts or like substances employed for absorbing moisture from the atmosphere, and is chiefly designed for use in musical instruments that are liable to injury from damp; or it may be placed in drawers, chemical balance cases, &c., for the same purpose, without any risk of damaging the articles which it is desired to keep dry.

A box constructed of sheet iron or any suitable material is formed of an outer and inner shell, the inner one being fixed in the outer so as to leave a space between the two shells. The inner shell holds the chloride of calcium or other hygroscopic substance, while the outer shell is adapted to receive and contain the liquid absorbed by the salt, and is so constructed that, should the box be upset, the liquid will not be spilled or thrown over the article with which it is being used. A sponge placed under the lid of the box affords further protection. Atmospheric air enters the box through holes in the lid, and any moisture which it contains will be absorbed by the salt. As the moisture is taken up the deliquescent crystals become liquefied and dribble through a hole in the bottom of the inner shell into the space between the two shells, the enclosed air escaping through a pipe.—E. S.

Improvements in or Pertaining to Drums or Vessels with Covers for containing Substances, such as Anti-fouling Compositions and Paints, having Constituents liable to Settle. V. B. Lewes, Greenwich. Eng. Pat. 1757, February 1, 1890. 6d.

See under XIII., page 150.

Improvements in the Purification of Water by Distillation. W. C. Young, Forest Gate. Eng. Pat. 7,840, May 20, 1890. *Id.*

THE water is mixed with an excess of lime or other non-volatile inorganic alkaline material, and, after either filtering or allowing to clear by subsidence, is distilled, the distillation being arrested before all the water passes over. Moreover, the first portions are rejected when water free from ammonia is required.—D. A. L.

Improvements in the Construction of Apparatus for Softening and Purifying Water. R. S. Brownlow, Manchester. Eng. Pat. 16,906, October 2, 1890. *6d.*

THIS invention relates chiefly to apparatus employed in the purification of water by the addition of chemical reagents, which cause the precipitation in a solid or flocculent form of the impurities contained therein, but it is also applicable to the purification of any fluid containing precipitable matter, and the object of the invention is to provide baffling plates which shall compel the fluid to take a much more devious course than usual, and shall present a greater number of precipitating surfaces. To effect this, a vertical vessel (preferably cylindrical) encloses a series of plates forming passages sloping alternately upwards and downwards, and combined with a vertical division so arranged as to cause the fluid to rise through the vessel with an upward and downward motion, and at the same time with either a continuously circulating, or alternately reversed motion.—E. S.

Improvements in Vacuum Pans. F. H. Flottmann, Bochum, Germany. Eng. Pat. 16,461, October 16, 1890. *6d.*

THE apparatus, which is adapted for concentration, extraction, desiccation, &c., practically consists of two cylindrical or globular vessels, one fitted to revolve inside the other. The inner one, which is intended for holding the material to be treated, is mounted, by means of hollow trunnions working in stuffing-boxes in the outer cylinder, in such a manner that it can be exhausted and rotated independently of the other cylinder or jacket. The latter is likewise capable of a partial movement on trunnions (situated in a plane at right angles to the stuffing-boxes), these trunnions, being hollow, also serving for the introduction of steam, &c., into the space between the two vessels. The partial movement (horizontal to vertical) of the outer jacket, and consequently of the whole apparatus, is produced by worm gearing, and its object is to enable the inner vessel to be charged through one of its trunnions, the other trunnion being suitably connected with the exhaustor, gauge, &c. The stuffing boxes, it will be seen, are in a horizontal plane while the inner vessel is being rotated. For details the original drawings must be consulted.—O. H.

A New or Improved Manufacture of Artificial Stone or Composition and Building Blocks and other Articles thereof. F. Jurschma and R. R. von Gunesch, Vienna, Austria. Eng. Pat. 18,168, November 15, 1890. *Id.*

See under IX., page 141.

Improvements in Apparatus for the Enriching of Phosphate of Lime and of Phosphated Chalks for the preparation of Cements, Mortars and Starches, and for similar Purposes. A. Cajot, Brussels, Belgium. Eng. Pat. 18,732, November 12, 1890. *6d.*

THE material to be treated is crushed, mixed with water, and fed through a hopper to a cupped chain or band which carries it into a case divided into several water-tight compartments through which it passes in succession, being thrown through holes in the partitions so inclined as to project it towards the partition walls. Each of the compartments is provided with a cupped chain or band similar to that in the first, and is further divided at its upper part only by a partition.

At the lower part of this partition is a pipe supplying water for the washing process to which the material is subjected, and somewhat above this is an aperture whence the "water charged with lime, alumina, and other impurities" flows away. Of this apparatus it is stated that "it affords the advantage of immediately separating materials the specific gravity of which differs but slightly, but which wash out more or less perfectly in water on account of the porosity and of the tenacity of the molecules."—B. B.

II.—FUEL, GAS, AND LIGHT.

Apparatus for Charging and Drawing Retorts mechanically. J. Ruscoe, Hyde. Eng. Pat. 18,108, November 13, 1889. *1s. 6d.*

THE principal object of this invention is to reduce the shock on the body of the retort produced by charging large masses of coal. This is effected by means of a scoop constructed so that the two sides and the base can be moved both jointly and independently. The scoop, which is capacious enough to contain a full charge of the retort, is driven forward by suitable mechanism into the retort to the rear end. The bottom of the scoop is then withdrawn, depositing the coal in the retorts, and subsequently the sides are withdrawn. The sides are connected by cross-pieces or bows which prevent the retrograde movement of the bottom of the scoop from being communicated to the coal. The improvement in drawing apparatus consists of a mechanical sliding rake provided with a removable head and having a double oscillating motion so that the head of the rake may be moved in any direction within the retort.

The mechanism by which the various motions are imparted to the scoop and rake, and the details of construction, are fully described in the specification and illustrated by eight sheets of drawings.—S. B. A. A.

A Method of Enriching and Increasing the Volume of Gas obtained from Coal and utilising the Waste Heat from Retort Settings. F. Pritchard, Huyton Quarry. Eng. Pat. 18,163, November 14, 1889. *8d.*

THIS method is a modification of the Dinsmore process of manufacturing coal-gas, the main difference being that the reheating duct is placed outside the retort chamber in the brickwork above the arch. This duct is preferably a cast-iron chamber of rectangular section disposed parallel to the retorts and divided into two communicating compartments by a horizontal diaphragm extending from the door almost to the back of the duct. It is heated by the waste gases from the retort chamber, which pass through a flue piercing the arch and opening into a flue which envelops the bottom and portions of the sides of the duct and communicating past a damper with a pass-by flue which opens into the main flue; the enveloping flue likewise communicates past a damper with the main flue. The temperature of the duct is regulated by diverting the current of waste gases from the enveloping flue to any required extent by suitably adjusting the dampers. The coal-gas is conveyed from the retorts into a collecting chamber and thence past suitable valves into the lower compartment of the duct; it then passes from the upper compartment into the water-jacketed ascension main, &c., as is usual. As the enveloping flue does not surround the upper part of the duct the gas is less strongly heated during the latter half of its course.—S. B. A. A.

Improvements in the Distillation of Coal, Shale, and the like, the Invention comprising the production of a Special Description of Coke. T. Parker, Wolverhampton. Eng. Pat. 67, January 2, 1890. 8d.

THE objects of this invention are the increase in the quantity and value of the solid and liquid volatile derivatives from coal or shale, and the production of a porous variety of coke which will burn freely in an open fireplace. The coal is charged into a large chamber closed by a cup and cone and provided with tuyeres near the bottom, and is heated to a temperature of 550° — 650° C. by forcing or drawing through it a current of superheated steam, water-gas or other gas which will not support combustion to any material extent. An arrangement is described in which a portion of the products of distillation, freed from condensable products by passing over a tar-pit and through condensers, is in part burned in a regenerative stove, the remainder passing through the heated stove into the coal chamber, where it serves to raise the coal to the required temperature. Steam or water-gas may also be used to convey the heat from the stoves to the coal, a small portion only of the products of distillation being used for heating the stoves.

In another arrangement a portion of the products of distillation is mixed with air, ignited in a small combustion chamber and led into the coal chamber, the spent gases passing into the chimney by an opening a little above the level of the tuyeres. This process of distillation by internal heating may, it is alleged, be advantageously applied to the manufacture of ordinary coal-gas and common coke at the usual temperatures.—S. B. A. A.

Improvements in the Manufacture of Gas. W. T. Cotton, London, and E. F. B. Crowther, Manchester. Eng. Pat. 343, January 8, 1890. 6d.

THESE improvements are in the construction of vertical retorts. The retorts are tapered internally, their larger diameter being at the bottom, where each retort is supported on a shallow box or casing. The retorts are not closed below by the casings but the opening is continued downwards by corresponding apertures in the upper and lower plates of the casings and by a wide exit tube fastened to the under surface of the lower plate. The casings enclose a moveable draw-plate consisting of slabs of fire-resisting material bolted together and provided in places with apertures similar to those in the casing plates. During coking the coal in the retort rests upon the slabs, and the coke is discharged by advancing the draw-plate by suitable mechanism until its apertures are brought to correspond with those in the casing, when the coke falls through on to the barrows placed beneath the exit tube; the draw-plate is then moved back into its previous position. Air is prevented from entering the casing and gas from escaping by means of a pan containing water placed under the exit tube. This vessel is hinged to one side of the tube and fastened to the opposite side by a spring catch which can be released before discharging.—S. B. A. A.

Improvements in Artificial Fuel and in the Process of Making the same. W. B. McClure, E. Corning, J. E. McWilliams, and J. W. White, St. Paul, Minn., U.S.A., and T. Hodgson, Buffalo, New York, U.S.A. Eng. Pat. 15,012, September 23, 1890. 6d.

1,660 lb. of finely divided and heated culm or coal-dust, 100 lb. of sharp clean sand, 40 lb. of finely powdered well-burnt lime-dust are thoroughly mixed and incorporated by the aid of heat with 125 lb. of naturally solid asphaltum mixed whilst in a molten condition with 75 lb. of naturally liquid asphaltum or petroleum tar. The compost is pressed into blocks and cooled in a bath of cold water.

Utah Ozokerite. A. N. Seal. J. Franklin Inst. 1890, 100, 402—406.

UTAH ozokerite has not been fully investigated and the results obtained are somewhat conflicting. Newberry (Eng. and Mining J. March 22, 1879), Wurtz (Eng. and Mining J. July 1889), and Beilstein (Ber. 16, 1574), have previously published some details. The author describes this ozokerite as of a dark brown colour, wax-like in consistency with a foliated structure; crystals of gypsum were found with it. The material melts at 53° — 55° , the specific gravity being 0.9285; it is soluble in warm benzene, ether and carbon bisulphide, giving a fluorescent solution. On boiling with absolute alcohol a pure white solid hydrocarbon separated out in nearly scales; on combustion it was shown to consist of carbon, 85.44; hydrogen, 14.45. On melting it became yellowish, of waxy consistency with sp. gr. 0.9708, was soluble in all solvents for ozokerite and further in hot alcohol and hot acetone. Experiments showed that it was little acted on by strong sulphuric acid or by bromine, and was thus evidently a paraffin. The molecular weight by Raoult's method was 256.

Experiments with the ozokerite showed that it contained very few olefines, and was not readily acted on by reagents; the melting point and percentage composition pointed to a formula of $C_{25}H_{52}$, the molecular weight by the Raoult method would give about $C_{18}H_{38}$, the true formula probably lying between these two.—D. A. S.

PATENTS.

Improved Process and Apparatus for the Production of Best Hard Charcoal, together with the Simultaneous Recovery of Acetic Acid, Wood Spirit, Tar, Ammonia, Gas. L. Zwillingner, Vienna, Austria. Eng. Pat. 18,823, November 23, 1889. 8d.

HERETO the carbonisation of organic materials such as wood, peat, brewers' grains or refuse, lignite, bones and the like, has been effected in retorts by simply heating them or assisting this process by the injection of steam or other gases, as for instance, water-gas. The processes in which steam is used have the disadvantage that steam, being a gas easily condensed, is retained by charcoal by reason of surface attraction, and cannot therefore perform its object of removing the volatile products evolved in a sufficiently complete manner. Water-gas is more suitable for this purpose, but its use is inconvenient as it necessitates an apparatus for its production. In all these processes the introduction of air or free oxygen into the retorts must be carefully avoided. The object of this invention is to remove the above difficulties and actually, in contradistinction to these processes, by the application of atmospheric air, which is employed to make the steam more readily movable in the heated retorts containing the raw material. The air employed is passed through water and has its percentage of oxygen so reduced, and at the same time is so saturated with steam, that only carbonisation and not combustion is brought about. The steam with which the air is saturated is for this reason securely retained by the air and easily carried through the material to be carbonised, and can thus assist the formation of acetic acid and other volatile products. The apparatus for producing superheated air saturated with steam and rendered poor in oxygen is described in detail in the specification and illustrated by one sheet of drawings.

—D. B.

A Method of Separating the Isomers contained in Crude Nitrotoluene. M. Lange, Amersfoort, Holland. Eng. Pat. 1407, January 27, 1890. 4d.

THE process depends on the difference in the action of sulphonating agents on different nitrotoluenes. It has been found that in sulphonating crude nitrotoluene, the ortho-compound only is at first attacked, whilst the para-derivative remains unaltered. The inventor utilises this difference of reaction in view of producing the sulphonic acids of para- and orthonitrotoluene from crude nitrotoluene. He proposes to run fuming sulphuric acid, sulphuric anhydride or sulphuric monochlorhydrin slowly into the said mixture at a temperature not exceeding 100°. From time to time a sample is withdrawn for examination, and when it is found that only paranitrotoluene separates out in a solid state the addition of the sulphonating agent is stopped. The product is then poured into water and the soluble portion filtered off from the paranitrotoluene, or the latter is distilled off by means of steam. The sulphonic acid is then converted into solid form by conversion into the calcium salt or by other known means.—D. B.

IV.—COLOURING MATTERS AND DYES.

Induline. E. Isel. Chem. Zeit. 14, 1535.

THE author has prepared a blue colouring matter, first discovered by Caro, by heating together 2½ parts of aniline hydrochloride, 1 part of amido-azo-benzene hydrochloride, and 6 parts of water for 24 hours at 70–80° C. It is separated from the melt by solution in water, and the addition of salt. The new body is difficultly soluble in cold, easily soluble in hot water, forming a blue solution which possesses a reddish-brown fluorescence. It is also soluble in alcohol. Its solution dyes cotton prepared with tannin, or plain cotton in presence of sodium chloride or acetate, a splendid blue, which in the case of tannated cotton is extremely light-fast.

Wool and silk are dyed in a neutral bath, the former with a more reddish shade. The portion of the melt insoluble in water is partially soluble in alcohol, which extracts from it a beautiful grey-dyeing spirit-nigrosine, capable of conversion into a water-soluble nigrosine by means of sulphuric acid. The portion of the residue insoluble in alcohol consists of azo-phenine. The fact that the above bodies are produced at such a low temperature (50–70° C.) was certainly not previously known.—H. T. P.

Aniline Black. H. Gutknecht. Chem. Zeit. 14, 1557.

THE ordinary way of producing aniline black on the fibre consists in steeping the material in a solution of aniline hydrochloride and potassium chlorate, squeezing out the excess of solution, and drying the fabric at about 30° C., the oxidation being finished by a bath of hydrochloric acid and an alkaline chromate. During the first stage of the oxidation there is considerable danger of the material being injured by the fumes of hydrochloric acid that are produced, and the author therefore recommends the substitution of aniline potassium sulphate for the aniline hydrochloride. This double salt is prepared by adding the theoretical amount of aniline to a hot solution of potassium bisulphate and filtering. The solution, on cooling, deposits the double salt in large crystals. It is soluble in 6 parts of cold water, so that a cold saturated solution contains 7.5 per cent. of aniline, which is just about the correct quantity for producing aniline black on cotton. The potassium bisulphate formed during the course of oxidation does not attack the fibre as long as any moisture is present. The temperature of oxidation may also be considerably raised, thus leading to a considerable saving of time, and a better utilisation of the aniline.—H. T. P.

On a New Process for the Extraction of Indigotin from Commercial Indigo. T. M. Morgan. J. Amer. Chem. Soc. 1890, 12, 302.

THE following process yields pure indigotin in considerable quantities:—

Commercial indigo, finely ground and intimately mixed with about an equal weight of zinc-dust, is spread in layers about an inch deep on thin boards and introduced into a steam chest that can be made air-tight, with entry- and exit tubes for steam, and an aperture for the introduction of a solution of sulphurous acid. The air is expelled by a rapid current of steam, then the steam is nearly cut off, and sulphurous acid solution introduced a little at a time so as to keep the steam in the chest saturated; and this is continued till the reaction is completed. This takes place in from one to two hours, when the indigotin is completely reduced. The product is then of a dirty yellowish or greenish-yellow colour. It dries quickly on taking from the steam chest, and is then not liable to rapid oxidation, and may be kept for several days unchanged. Indigo white may be obtained from this mixture by treating with wood spirit in an extraction apparatus, or by digesting in flasks filled to the neck with this solvent. On exposure of the solution to the air in shallow vessels, the indigotin is precipitated in a pure and crystalline state. The yield is large and would probably be a theoretical one if sufficient precautions were employed.—P. J. H.

Industrial Society of Mulhouse. Meeting of November 12, 1890. Chem. Zeit. 14, 1675.

NÖLTING and Polonowsky find that tetra-methyldiamidobenzhydryl will condense not only with amines in which the para position is free, but also with para-substituted amines such as para-toluidine, meta-xylydine, pseudo-cumidine, &c. Condensation takes place in the meta-position to the group NH₂ if the process be carried out in presence of a large excess of concentrated sulphuric acid, but in the ortho-position if hydrochloric acid be present. The formula of the condensation products obtained with para-toluidine are—

and—

The former, on oxidation, yields a bluish-green; the latter is only oxidised if acetylated first and then gives a very blue-green. Nölting and Swarsinsky have condensed para-nitrodime-thylanidobenzhydryl with para-toluidine in an analogous manner. By acting on dimethylmetatoluidine with the three nitrobenzaldehydes the nitrotetramethyldiamido-tolylphenylmethanes were obtained—

All these bodies yield green dyes on oxidation. Of the amido bases obtained by reduction of these three nitro-bodies, the para-derivative gives a violet, the meta-derivative a green dye. The ortho-amido compounds must first be acetylated and then yields bluish-green dyes on oxidation, and methylmetatoluidine therefore behaves just like dimethyl-aniline towards the nitrobenzaldehydes, whereas meta-toluidine oxidised in presence of para-toluidine yields no coloured product. By condensation of nitrodime-thylanidobenzhydryl with meta-toluidine and dimethylmetatoluidine two bases are obtained—

and—

Both yield green dyes on oxidation. By condensation of dimethylmetatoluidine with ortho-formic ether, $\text{CH}(\text{OC}_2\text{H}_5)_2$, Nölting and Trautmann have obtained hexamethyltriamido-tritylmethane, $\text{CH}(\text{C}_6\text{H}_5\text{N}(\text{CH}_3)_2\text{CH}_3)_3$ and by oxidation of this body a pure blue colouring matter. Nölting and Freyes have acted with benzhydrol on *o*-toluylenediamine and obtained a tetramido-derivative of triphenylmethane—

which on oxidation yields a greenish blue. On treating this body with phenantrenquinone, an azine results, which may be oxidised to a green dye.—A. R.

PATENTS.

Manufacture of Sulpho-Acids and Colouring Matters therefrom. F. Wirth, Frankfort-on-the-Maine, Germany. From the "Farbenfabrik vormals Brönnner," Frankfort-on-the-Maine, Germany. Eng. Pat. 3724, August 4, 1882. Amended May 2, 1890. 6d.

The original specification has already been abstracted (this Journal, 1889, 700). The patent refers to the production of naphthylamine sulphonic acids by heating the naphthol sulphonic acids with ammonia. In the amendment attention is called to the fact that the derivatives of β -naphthol are more easily converted than those of α -naphthol, and that the reaction takes place at high temperatures only. The production of "another β -naphthylamine sulpho-acid" is disclaimed, and also the combination of the diazo-compounds of the naphthylamine sulphonic acids with the phenol ethers.—T. A. L.

Improvements in the Manufacture of Colouring Matters. G. W. von Nawrocki, Berlin, Germany. From P. Böttiger, Lodz, Russia. Eng. Pat. 4415, March 5, 1884. Amended May 2, 1890. 6d.

A PROCESS for obtaining colouring matters which dye wool and unmordanted cotton red by combining the salts of tetrazodiphenyl with α - or β -naphthylamine or their sulphonic or disulphonic acids. The use of the β -naphthylamine- α -sulphonic acid and of the γ -disulphonic acid is disclaimed in the amendment.—T. A. L.

The Production of New Azo-Colouring Matters. A. G. Green and T. A. Lawson, London. Eng. Pat. 14,304, September 10, 1889. 6d.

By reducing *p*-nitro-*o*-toluidine of melting point 107°C . in an alkaline solution with sodium stannite it is converted into azoxytoluidine (Limpricht, Ber. 18, 1403). If an alcoholic solution be employed, azotoluidine is produced. Both these bodies when diazotised combine with the sulphonic acids of phenols and amines to form colouring matters capable of dyeing unmordanted cotton. A bluish-red dyestuff is formed by combining diazotised azoxy-*o*-toluidine with α -naphthol-*p*-sulphonic acid (corresponding to Piria's naphthionic acid).—T. A. L.

Improvements in the Production of Azo-Colouring Matters. R. J. Friswell and A. G. Green, London. Eng. Pat. 134, January 3, 1890. 4d.

OXY-azo-TOLUIDINE of melting point 212°C . (Limpricht, Ber. 18, 1405), when diazotised and combined with amines, phenols, and their sulphonic or carboxylic acids,

yields dyestuffs. When combined with α -naphthol-*p*-sulphonic acid (corresponding to Piria's naphthionic acid), the colouring matter dyes unmordanted cotton red from a neutral or alkaline bath.—T. A. L.

Improvements in the Manufacture of Blue Colouring Matters. A. Kern and E. Sandoz, Basle, Switzerland. Eng. Pat. 569, January 11, 1890. 6d.

The products obtained by the action of gallocyanine on aniline and its homologues are insoluble in water (Ber. 21, 1741; this Journal, 1888, 559). By sulphonating these compounds with ordinary sulphuric acid or acid containing anhydride they are rendered soluble, and dye blue shades on silk and wool without a mordant and cotton mordanted with chromium salts. The compounds formed by the action of aniline and its homologues on the products obtained by reacting with nitrosodimethylaniline hydrochloride on gallic acid or its methyle ether and similar substances can also be sulphonated and employed for dyeing as above.—T. A. L.

The Production of Diorynaphthalinemonosulpho Acid and of Disazo Dyestuffs from the same. A. Bang, Leeds. From Dahl and Co., Barmen, Germany. Eng. Pat. 735, January 15, 1890. 4d.

The α -naphthylamine disulphonic acid of which the lime salt is soluble in 80 per cent. alcohol yields, when fused with caustic soda, a dihydroxynaphthalenemonosulphonic acid which can be combined with the tetrazo compounds from benzidine, toluidine, diamido-stilbene, diamido-carbazol and dianisidine to form violet to blue cotton colouring matters. The dihydroxynaphthalene sulphonic acid is produced as follows: 30 kilos. of sodium α -naphthylamine disulphonate are added at a temperature of about 180°C . to a solution of 110 kilos. of caustic soda and 20 litres of water. The temperature of the melt is afterwards raised to 200° – 220° and maintained for 8–10 hours. It is then dissolved in 400 litres of water and 300 kilos. of 30 per cent. hydrochloric acid added. After filtering and cooling nearly the whole of the dihydroxynaphthalene sulphonic acid separates out. To obtain dyestuffs from it 26 kilos. of the acid and 40 kilos. of sodium carbonate are dissolved in water, and to this is added a solution of the tetrazo compound obtained by diazotising 10.5 kilos. of toluidine (or an equivalent quantity of benzidine, diamido-stilbene, diamido-carbazol or dianisidine) with 30 kilos. of hydrochloric acid and 7 kilos. of sodium nitrite. After standing 24 hours the dyestuff is filter-pressed and dried.—T. A. L.

Manufacture of Azo-amines by the Reduction of Azo-Colouring Matters derived from Nitramines. J. Imray, London. From "La Société Anonyme des Matières Colorantes et Produits Chimique de St. Denis," A. F. Poirrier and D. A. Rosenstiehl, Paris, France. Eng. Pat. 1579, January 29, 1890. 6d.

A METHOD for obtaining diamido-azobenzene (*p*-azo-aniline) and its homologues by combining a nitro-amine with a phenol or amine and reducing the azo compound thus formed in an alkaline solution. The following example is given: *p*-nitraniline is diazotised and combined with naphthol disulphonic acid. 100 kilos. of the colouring matter thus obtained are dissolved in 1,000 litres of water and 100 litres of caustic soda of 40°B . The temperature is raised to 50°C . and 80 kilos. of glucose of 75 per cent. are added. The mixture is then boiled, when the violet colour of the liquor gradually changes to brown. After cooling, the *p*-azo-aniline separates in crystalline needles and may be purified by dissolving in hydrochloric acid, filtering and precipitating with soda. The *p*-nitraniline may be replaced by *m*-nitraniline or by equivalent quantities of the corresponding derivatives of toluidine, xyldine, &c. Any alkaline reducing agent may be employed and the phenol or amine with which

the nitramine is combined may be a sulphonic acid or not, but it is preferable to select those combinations which are soluble in water in presence of alkalis.—T. A. L.

Improved Manufacture of Colouring Matter of the Induline Series Soluble in Water. O. Imray, London. From the "Farbwerke vormals Meister, Lucius und Brünig," Höchst-on-the-Maine, Germany. Eng. Pat. 1699, January 31, 1890. *Id.*

THE following compounds have been separated from the induline melt obtained by heating together a mixture of aniline, its hydrochloride and amido-azo-benzene.

1. A soluble induline, $C_{24}H_{16}N_4HCl$, the base of which forms stable salts with organic acids soluble in water.

2. An induline soluble in spirit, of which the base does not form salts with organic acids. As already described in Eng. Pat. 16325 of 1888 (this Journal, 1889, 878), the induline mentioned under (1.) yields colouring matters of the induline series soluble in water when heated with aromatic *m*- and *p*-diamines. In a similar manner soluble colouring matters are obtained from the induline mentioned under (2.) by heating it with aromatic diamines, and preferably with *p*-phenylenediamine. 100 kilos. of induline, 150 kilos. of *p*-phenylenediamine, and 30 kilos. of *p*-phenylenediamine hydrochloride are heated to 180° C. for about three hours. The excess of *p*-phenylenediamine is extracted by boiling water and the residue dissolved in 2,000 litres of hot water and 70 kilos. of 30 per cent. hydrochloric acid. After filtering, the colouring matter is precipitated by the addition of salt. It dyes cotton blue.—T. A. L.

Production of Yellow Dye or Colouring Matter. T. R. Shillito, London. From J. R. Geigy and Co., Basle, Switzerland. Eng. Pat. 1774, February 1, 1890. *Id.*

DIHYDRO-THIO-*p*-TOLUIDINE sulphonic acid or primuline (polychromine), both bodies being formed by the action of sulphur on *p*-toluidine and subsequent sulphonation, yield, when their diazo compounds are boiled with ammonia, colouring matters which dye un mordanted cotton yellow. 50 kilos. of primuline are dissolved in 1,000 litres of water, 30 kilos. of hydrochloric acid of 20.5 B. are added, and the solution diazotised by the addition of 7 kilos. of sodium nitrite. 30 kilos. of ammonia of 25 B. are then added, and after standing about 12 hours the solution is boiled and the colouring matter precipitated by the addition of salt. It forms a brown powder easily soluble in water. The yellow colour on the cotton fibre is changed by caustic alkalis to an orange red (see also this Journal, 1890, 854 and 1032).—T. A. L.

Production of Yellow Basic Colouring Matter. O. Imray, London. From "The Society of Chemical Industry in Basle," Switzerland. Eng. Pat. 1808, February 3, 1890. *Id.*

WHEN *m*-toluylenediamine is heated with oxalic acid in presence of a condensing agent such as zinc chloride, it is converted into the base of a yellow dyestuff soluble in hydrochloric acid with the formation of the hydrochloride which dyes silk and cotton mordanted with tannin a bright yellow. 2.3 kilos. of *m*-toluylenediamine, 2.3 kilos. of dry oxalic acid, 1.5 kilos. of glycerol, and 1.8 kilos. of zinc chloride are heated with constant agitation to about 130° C., and afterwards to 160° C., for 3–4 hours. The melt is then dissolved in 16 kilos. of hydrochloric acid of 25 per cent., and diluted with 8 litres of water, when the colouring matter separates out. In order to purify it, it is dissolved in boiling water and precipitated with salt.—T. A. L.

Improvements in the Manufacture of Colouring Matters. R. Holliday, Huddersfield. Eng. Pat. 1814, February 3, 1890. *Id.*

A process for sulphonating the product obtained by heating 3 parts by weight of sulphur with 1 part by weight

of *p*-toluidine for 12 hours to 200°–250° C. after removing the dehydrothiololuidine from the melt by treatment with hot dilute hydrochloric acid. One part by weight of the base is added to 3–4 parts of fuming sulphuric acid containing 30 per cent. of anhydride, and the mixture agitated until a sample dissolves to a clear solution in water. The sulphonation may be accelerated by warming, and when complete the melt is poured on to ice or into water and salted out or diazotised directly and combined with phenols or their sulphonic acids to form dyestuffs.—T. A. L.

Improvements in the Manufacture of Azo-Colouring Matters for Dyeing and Printing. B. Willeox, London. From the "Farbenfabriken vormals Fr. Bayer und Cie.," Elberfeld, Germany. Eng. Pat. 1828, February 3, 1890. *Id.*

AN extension of Eng. Pat. 8299 of 1889 (this Journal, 1890, 608) substituting for the α -naphthylamine there mentioned the ethyl and methyl ethers of α -amido- β -naphthol. The following process yields a greenish-blue mordant dyestuff. Amido-sulpho-salicylic acid is diazotised and combined with an ether of α -amido- β -naphthol at about 50° C. The amido-azo compound obtained is filtered off, dissolved in alkali, and diazotised with sodium nitrite and hydrochloric acid. A black precipitate which first forms changes to red, and after filtering off is added to an alkaline solution of β -naphthol with the formation of the dyestuff.

—T. A. L.

Production of Soluble Blue Colouring Matters of the Induline Class. J. Imray, London. From "La Société des Matières Colorantes et Produits Chimiques de St. Denis" and Dr. Chapuis, Paris, France. Eng. Pat. 1874, February 1, 1890. *Id.*

By heating *p*-azoxyaniline, aniline, and aniline hydrochloride to 160–180°, and treating the melt with water and hydrochloric acid, the hydrochloride of an induline is formed which can be precipitated by salt and zinc chloride. The product dyes cotton mordanted with tannin violet-blue, which is said to be fast to soap or light. In place of aniline other aromatic amines may be employed.—T. A. L.

Improvements in the Manufacture of Soluble Blue Cotton Dyestuff or Colouring Matter. H. H. Lake, London. From K. Oehler, Offenbach-on-the-Maine, Germany. Eng. Pat. 2199, February 15, 1890. *Id.*

By heating so-called spirit induline with *p*-phenylene or *p*-toluylene diamine to 175° C., it is converted into a blue colouring matter soluble in water. The same process can also be applied to the induline obtained by heating together aniline, its hydrochloride, nitrobenzene, and an iron salt. The colouring matters are very easily soluble in water, but insoluble in brine. They dye cotton an indigo blue shade, which becomes darker by treating the dyed fibre with chromates.—T. A. L.

Improvements in the Manufacture of Colouring Matters. H. H. Lake, London. From A. Leonhardt and Co., Mühlheim-on-the-Maine, Germany. Eng. Pat. 3098, February 26, 1890. *Id.*

SUBSTITUTED naphthylenediamines are obtained by heating primary aromatic amines with dihydroxynaphthalene of melting point 216 in presence of a suitable condensing agent. The dihydroxynaphthalene is formed by fusing β -naphthalene disulphonic acid or Schaeffer's β -naphthol sulphonic acid, with alkalis. The substituted naphthylenediamines when heated with *p*-nitroso derivatives of aromatic amines or with quinone dichloro-imide in a suitable solvent yield basic green colouring matters.—T. A. L.

Improvements in the Manufacture of Colouring Matters.
The Clayton Aniline Company and John Hall, Manchester.
Eng. Pat. 5155, April 2, 1890. 6d.

DYESTUFFS of the benzidine series are according to this specification obtained by combining tetrazo-diphenyl or tetrazo-ditolyl with one molecule of the sulphonic acids of phenyl- and *o*-tolyl- β -naphthylamine referred to in Eng. Pat. 10,934 of 1889 (this Journal, 1890, 853) and reacting with these intermediate compounds on sodium naphthionate or in general on phenols, amines, their sulphonic and carboxylic acids.—T. A. L.

Improvements in the Production of Mixed Azo-Colours.
C. A. Martius, Berlin, Germany. Eng. Pat. 2213,
February 15, 1886. Amended April 26, 1890. 6d.

ALREADY abstracted (see this Journal, 1889, 701). The employment of several substances is now disclaimed and there are some clerical amendments.—T. A. L.

A Process for the Production of a Substantive Cotton Colour. J. Dawson and R. Hirsch, Huddersfield. Eng. Pat. 14,432, September 13, 1890. 4d.

IN Eng. Pat. 3803 of 1885 (this Journal, 1886, 96) a process is described for the production of colouring matters by the action of a salt of tetrazo-ditolyl on naphthionic acid. The present patent refers to an improvement on the method there mentioned by using an excess of naphthionic acid (4–6 molecules) to that previously employed. The following quantities are given:—10 kilos. of *o*-tolidine are dissolved in 30 kilos. of 30 per cent. hydrochloric acid and 200 litres of water and diazotised at a temperature below 10° C. by the addition of 75 litres of water containing 6.7 kilos. of sodium nitrite. The diazo solution is then added to 900 litres of water containing 90 kilos. of commercial naphthionic acid and the mixture allowed to stand six days. The black precipitate which forms gradually becomes reddish yellow and turns brilliant scarlet on the addition of caustic soda. When no further change of colour is observed, 1,000 litres of water are added, the mixture is made alkaline by the addition of 20 kilos. of 30 per cent. caustic soda lye and the temperature raised to 80° C., when the colouring matter is precipitated by adding 100 kilos. of salt, after which it is filter-pressed and dried. The mother liquor contains the excess of naphthionic acid which may be recovered by precipitation with hydrochloric acid.

—T. A. L.

Manufacture of Colouring Matters Obtained by the Action of Amines of the Fatty Series upon Galloeyanine.
J. Imray, London. From "La Société L. Durand Huguenin et Cie.," Basle, Switzerland. Eng. Pat. 18,526, November 17, 1890. 4d.

BLUE to green dyestuffs are formed by heating galloeyanine with primary and secondary amines of the fatty series in a concentrated aqueous solution at a temperature of 90°–100° C. The product is then dried and differs from galloeyanine in being easily soluble in water. The colouring matters dye mordanted and unmordanted wool and can also be employed for printing on cotton and for the formation of lakes.—T. A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

PATENTS.

Improved Apparatus for the Preparation of Textile and Filamentous Materials intended to Facilitate their Cleaning and the Removal of Thistles or Burrs therefrom. S. Pegler, Roubaix, France. Eng. Pat. 17,882, November 9, 1889. 6d.

A SERIES of rollers, working in pairs, is furnished longitudinally with metallic blades. The speed of the rollers increases from pair to pair, and the textile materials which are brought between the rollers are thereby drawn out and opened and the burrs and other foreign matters loosened which can then be easily extracted by the usual methods.

—H. S.

A New or Improved Machine or Apparatus for Finishing Textile Fabrics. G. Douglas, Bowling. Eng. Pat. 18,772, November 23, 1889. 8d.

TWO endless cloths, one placed over the other and heated by being brought into contact with steam cylinders, cover the greater part of a large cylinder. Fabrics to be pressed and finished are placed between the two cloths while in motion, the pressure being regulated by the tension of the cloths.—H. S.

Improvements in the Treatment of Hemp, Flax, Jute, Cotton, and other Substances, in Order to Preserve the Same. E. T. Truman, London. Eng. Pat. 19,773, December 9, 1889. 4d.

SUBSTANCES, such as the peroxides of manganese, lead, barium, &c., which have the property of decomposing ozone into oxygen, are stated to preserve hemp, flax, gutta-percha, india-rubber, and other similar substances from oxidation and decay. In practice these peroxides are mixed with ozokerite, tar, and other substances, and then applied to the materials to be protected, *e.g.*, sail cloths, tarpaulins, packing used for electrical conductors, cables, &c.—H. S.

An Improved Method of and Apparatus for Treating Wool in the Bating and Carding Processes preparatory to Spinning. A. J. Pilard, Paris, France. Eng. Pat. 20,386, December 18, 1889. 8d.

IN this process water is substituted for fatty matter in the preparation of wool, during the whole carding process up to the spinning. All the machinery is therefore treated with red lead, and the teeth of the cards made of tinned steel or aluminium bronze, to prevent oxidation. The wool is first subjected to two bating processes, then moistened with half its weight of water, left to stand 48 hours, and then carded, during which operation it is repeatedly moistened by means of apparatus between the cards, to keep up the hygrometric condition which is acknowledged to be the best for the carding of wool. When wool, carded thus, is subjected to the combing process, a considerable decrease of noils, and therefore increase of the combing wool, is effected. This process is also applicable to wool mixed with other fibres.—H. S.

Improvements in the Treatment of Textiles by Means of Ammoniacal Oxide of Copper for the Purpose of Rendering same Waterproof and Non-Combustible.
C. Baswitz, Berlin, Germany. Eng. Pat. 20,665, December 23, 1889. 4d.

TEXTILES are thoroughly impregnated with a solution of vegetable parchment in cuprammonium, and become possessed of all the qualities of parchment. The mechanical process is the same with that previously described in Eng. Pat. 16,708 of 1889 (compare this Journal, 1890, 1047).

—H. S.

Improvements in the Method of and Apparatus for Treating or Scouring and Washing Wool and other Fibrous Substances. John Smith, Isaac Smith, and Joseph Smith, Siddall. Eng. Pat. 1461, January 28, 1890. 8d.

SEVERAL scouring vessels are placed on different levels, and made to communicate with each other by tubes at the bottom. Above them other vessels are placed, having perforated bottoms through which the scouring liquor falls as a spray or shower into the vessels below. The wool is carried through the different vessels on endless travelling lattice sheets, and is thus exposed to the spray of the scouring liquor. At the end of each vessel a pair of rollers squeezes the liquor from the wool before it enters the next vessel. The liquor may be pumped into the upper vessel and utilised again. The construction of the apparatus may be modified by dispensing with the travelling lattice and allowing the wool to float in a long vessel filled with scouring liquor. Wool and liquor move slowly in one direction, and at the end of the vessel a pair of rollers squeezes the wool free of the liquor which falls into a vessel below, from which it can be raised by pumps into the upper vessel and re-used. A series of perforated revolving cylinders regulate the motion of the wool and liquor. By this process the felting and entangling of the material is avoided, whilst the cleansing is satisfactorily performed.

—H. S.

Improvements in the Process of Cleaning and Extracting Oil and Grease from Cotton-Waste and other Fibrous Materials. D. Barnett, St. Peter's Park. Eng. Pat. 1652, January 30, 1890. 8d.

COTTON-WASTE, after being used for cleaning engines and machinery, is treated with petroleum or other liquid hydrocarbon, by being placed in a cylinder of wire-work which revolves in a cylindrical vessel containing the petroleum. After treatment the waste is removed from the bath, and the petroleum expelled from it by pressure or other means, when the waste is washed with a suitable agent such as solution of soap, caustic, or other detergent, and turpentine. The waste is now rinsed with water and dried, when it is fit for re-use. The petroleum, after having taken up sufficient oil or grease, is separated in the usual way.—K. E. M.

An Improved Process for Washing and Scouring Wool and Fibrous Materials containing Grease. G. W. Arnott, P. A. Olivier, and G. Seagrave, London. Eng. Pat. 5482, April 10, 1890. 8d.

POTASH, sand, and other mineral matters present in the material are removed in a centrifugal machine by means of jets or sprays of water, operating in the centre of the machine. The oily and fatty matters are then extracted by carbon bisulphide, benzene or ether, the material being afterwards carefully washed with water. The fibres are said to be rendered softer than by the ordinary treatment, and a less quantity of the above-mentioned solvents required. The apparatus used for this process is a hydro-extractor which rotates first slowly and afterwards quickly, during each of the three parts of the operation, until the material is clean and dry. It is connected with a series of separators, where the sand and the earthy matters are deposited, the dissolved substances flowing into tanks and distilling vessels, where they are treated in the ordinary way. The hydro-extractor is suitably cased in to prevent the escape of volatile substances.—H. S.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

A "Discharge" for Dyes Mordanted with Chromic Oxide. H. Schmid. Chem. Zeit. 14, 1439—1440.

DYES fixed on the fibre by means of chromium sesquioxide are daily gaining in importance, owing to their relatively great stability and soap-fastness. A great variety of shades is obtainable by employing the numerous phenolic and other dyes that form lakes with chromium oxide, such as Gallocyanin, Coerulein, Alizarin, Alizarin-blue, -orange, -green, -black, -grey, &c. Designs are most readily -yellow, produced on materials so dyed by using a suitable discharge, the patterns obtained being distinguished for sharpness and cleanness. In the process hitherto employed the mordant is directly precipitated on the fibre by soaking the latter in a solution of chromium oxide in soda ($\text{Cr}_2(\text{NaO})_6$); or the material is soaked in chromium bisulphite and subsequently dried by heat. Again, a solution of a chromium salt may be used, followed by a bath of sodium zincate. The design is then printed on the fabric with an acid discharge, and the material is finally dyed with one of the above dyes. In order to effect a more rapid and complete discharge of the mordant, the author employs the following mixture:—

	Grms.
Water.....	9,000
"British Gum".....	7,000
Potassium ferriyanide.....	6,000
Potassium chlorate.....	600
Sodium chlorate.....	600
Magnesium carbonate paste.....	12,000

Coloured patterns are obtained by mixing potassium ferriyanide, magnesium carbonate, and alkaline chlorates with a suitable mineral colouring matter, such as chrome yellow, vermillion, &c., thickened with albumen. The fabric, previously prepared with a mixture of mordant and dye and dried (but on which the colour has not been developed), is printed on with the above composition and steamed. Below are formulæ for some dischargeable colours:—

VIOLET.

	Grms.
Gallocyanin in powder.....	120
Soda lye at 10° B.....	320
Water.....	24,000

When dissolved, add in the cold with stirring—

Sodium bisulphite at 36° B.....	400
Cold water.....	14,000

Finally add—

Chromium acetate at 20° B.....	400
Calcium acetate at 15° B.....	240
Water.....	920

and finally dilute the whole to 40 litres.

BLUE.

	Grms.
Alizarin blue S.....	120
Water.....	23,000
Sodium bisulphite.....	100
Chromium acetate.....	210
Calcium acetate.....	100

GREY.

	Grms.
Alizarin blue S.....	120
Water.....	23,000
Sodium bisulphite.....	180
Chromium acetate.....	210
Calcium acetate.....	100
Extract of Persian berries at 30° B.....	53
Alizarin, SX (20 per cent.).....	31
Nitro-salazarin.....	5

—H. T. P.

New Dyes. Chem. Zeit. Rep. 14, 334.

Pyromine is prepared by oxidation of tetramethyldiamidodiphenylmethaneoxide, which dyes tannin-mordanted cotton a brilliant blue-red, and surpasses all known dyes of similar shade for fastness. The dye can also be used for silk, jute, leather, paper, lakes and pigments.

Acridine Orange is another dye prepared by condensation of formaldehyde and *m*-tolylenediamine, and dyes cotton mordanted with tannin and tartar emetic a fast and brilliant orange. Silk is dyed in a soap-bath with acetic acid. Leather and jute require no mordants.—A. R.

New Method for Producing White and Buff Discharges on Indigo Grounds. W. Geller. Farber. Zeit. 2, 24.

THE goods are printed with 300 grms. of dextrin thickening, 150 grms. of sulphate of lead, 40 grms. of sodium chlorate, 42 grms. of ammonium chloride, and 19 grms. of potassium ferrieyanide. The salts are best dissolved at 40°–50° in the gum, the sulphate of lead being added last. After printing, the goods are steamed with dry steam for half an hour, then passed through a solution of 30 grms. of caustic soda of 38° B. per litre of hot water, and in case the whites are yellowish, through very dilute sulphuric acid. Instead of the ferrieyanide, potassium bichromate may be used. In this case, passage through sulphuric acid can be dispensed with.

The buff is produced by boiling 130 grms. of leio-gum, 60 grms. of starch, 65 grms. of sodium chlorate, and 250 grms. of water, then adding 70 grms. of ammonium chloride and 40 grms. of potassium ferrieyanide at 40°–50°, and finally, 220 grms. of lead sulphate, 16 grms. of oxalic acid, 100 grms. of ferric acetate (prepared from 20 grms. ferric chloride and the corresponding amount of sodium acetate). After printing, the goods are passed through the Mather-Platt steaming chamber, treated with ammonia to neutralise the oxalic acid, steamed, and passed through caustic soda as above.—A. R.

PATENTS.

Improvements in the Treatment of or Finishing of Manufactured or Partially Manufactured Materials from Cotton or similar Fibres or other Substance containing Cellulose. H. A. Lowe, Heaton Moor. Eng. Pat. 20,314, December 17, 1889. 6d.

THE material is immersed for several minutes in a concentrated solution of sodium hydrate (usually of 40° to 55° Tw.), then squeezed and thoroughly washed with warm water. By this treatment the fibres are said to become more cylindrical, and their walls thicker. The material itself being thereby rendered stronger, can be dyed better and more uniformly.

—H. S.

An Improved Process and Composition for Producing Printing Ink. C. Huelser, London. From G. Callmann, Weimar, Germany. Eng. Pat. 20,830, December 28, 1889. 4d.

USE is claimed of the powder produced by grinding brown coal (to pass through a sieve of at least 3,500 meshes per square centimetre), instead of soot, &c. hitherto used, for making black printing ink. The ink made with powdered coal is said to be characterised by its "intensely black velvety shade."—E. B.

Improvements in Apparatus for Treating Fabrics, Paper, and other Materials with Gases, Steam, or Hot Air. E. Remy, Mülhausen, Germany. Eng. Pat. 20,905, December 30, 1889. 8d.

THE material is carried through the chamber in which it is to be treated by two travelling endless chains, arranged parallel to each other, and provided with arms or levers,

each adapted to turn about a centre, two arms constituting a set, and in corresponding positions on the two chains, and connected by a bar or roller that is capable of being turned over by means of turnstiles placed near the entrance to the chamber, and operating in such a manner that all the bars are brought in succession underneath the entering material, and cause it to be automatically formed into long folds that hang down side by side, thus exposing a large surface to the action of the gases, steam or hot air within the apparatus, the material being afterwards straightened out at the opposite end of the chamber. The apparatus may be partly or entirely closed, openings being however provided for the material to enter and leave, and also for means to actuate the parts within the apparatus.—E. S.

Improvements in the Production of Azo-Colours upon Cotton or other Vegetable Fibre in the Piece, and in Apparatus therefor. S. and J. Knowles, Tottington. Eng. Pat. 1062, January 21, 1890. 8d.

THE diazotising baths employed in the production of azo-colours on cotton piece-goods, are extremely sensitive, and rapidly rendered inoperative by the passage through them of cloth prepared with phenols. To overcome this difficulty, the present inventors run the piece continuously through the machine shown in the Figure, to which the diazo solution

PIECE-DYEING WITH AZO-COLOURS.

is supplied in quantity as required, by means of the spurt pipes *d, d*. The lower series of rollers *e, e, e*, are preferably composed of metal, and are supported in a shallow vessel *e*, which serves to receive the liquor not absorbed by the cloth, the operation being so regulated that only a small quantity of such liquor is at any time in the receiving vessel.—E. B.

Improvements in the Manufacture of Colouring Matters, and in Dyeing or Printing Wool and other Fibres therewith. R. Holliday, Huddersfield. Eng. Pat. 1812, February 3, 1890. 4d.

A NITROSO- or dinitroso-compound of one of the dihydroxynaphthalenes is reduced in an aqueous solution with sodium hydrosulphite or other suitable reducing agent. The fibre is then immersed in the bath and, after the superfluous liquid has been removed, is oxidised by exposure to the air. The colouring matter may also be obtained as a paste or powder by oxidising the bath itself and collecting the precipitate. In order to employ it for dyeing it is mixed with water and reduced with hydrosulphite as above, or the reduced compound may be thickened with gum or starch and used for printing, the colour being subsequently developed by steaming.—T. A. L.

Improvements in or appertaining to Dyeing with Indigo.
J. Braithwaite, Kendal. Eng. Pat. 2195, February 11, 1890. 6d.

The inventor claims as an improvement in dyeing with indigo, the omission of any addition of "alkaline carbonate or other like salt," the vat being formed by the reduction of indigo with hyposulphurous acid, and being "neutral or somewhat acid," instead of alkaline as hitherto. Such a vat is prepared by taking, for example, 20 lb. of indigo, 10 lb. of zinc-dust, and 15 lb. of sodium bisulphite. The ingredients named may be mixed together in a dry state to form powders or cakes which may be kept for months and merely require mixing with warm water to form a dye-vat. Sodium sulphite may be substituted for sodium bisulphite in these dry mixtures, a sufficient amount of mineral acid being added to the water to produce sodium bisulphite when such is the case.—E. B.

Apparatus for Dyeing and otherwise Treating Textile Fibres in the Form of Bobbins or Cops. W. L. Wise, London. From F. Mommer and Co., Barmen-Rittershausen, Germany. Eng. Pat. 2763, February 20, 1890. 8d.

The cops are packed in regular layers as closely as possible in rectangular boxes, and the spaces between the layers filled up with india-rubber or a similar material, in order to obtain an even resistance in the dyeing bath, which is necessary for dyeing the cops uniformly. The dyeing liquid is forced through the bottom of the boxes by considerable pressure, and passing through the material escapes through the covers, and subsequently returns to the pump. The material is then washed with water in a similar way. The material is freed from the dye liquid or water by placing the boxes, each having its perforated bottom turned outward, on a specially constructed centrifugal machine, or by forcing a current of heated air through the bottom of the boxes.—H. S.

An Improved Ink for Printing and similar Purposes.
H. H. Lake, London. From W. G. Fuerth, Newark, New Jersey, U.S.A. Eng. Pat. 16,689, October 20, 1890. 4d.

VASELIN is combined with boiled oil or other fatty substance and colouring matter to form a concentrated printing ink, which possesses the advantages of not clogging or hardening on ordinary roller-composition, of printing smartly, without spreading or flowing, and of not leaking from its packages; it is rendered of the proper consistency for printing by the friction of the rollers over it.—E. B.

VII.—ACIDS, ALKALIS, AND SALTS.

The Decomposition of Strontium Carbonate by Heat.
J. T. Conroy.

See pages 101—106.

The Manufacture of Potassium Carbonate from the Crude Residue of Beetroot Molasses, with the Preparation of Potassium Chloride, Potassium Sulphate, and Sodium Carbonate. W. Greif. Chem. Zeit. 14, 1410—1442, 1504—1505, and 1535—1537.

The composition of the crude calcined residue of beet molasses is extremely variable. The chief constituent, potassium carbonate, ranges from 25 to 60, and averages 40 per cent. A very good sample had the following composition:—

	Per Cent.
Potassium carbonate	45.5
Sodium carbonate	12.2
Potassium sulphate	2.6
Potassium chloride	10.5
Water	2.1
Insoluble matter	6.8
	100.0

The apparatus to be employed in working up the crude ash depends on the percentage of insoluble matter contained in it. Samples having not more than 10 per cent. of insoluble matter are treated in the following arrangement of wrought iron vessels (Fig. 1). B is a dissolving tank of 12 cbm. capacity, placed at a suitable height, say 4 m., above the floor. A cast-iron bend, closed by a wooden plug, is screwed into the bottom of the vessel. C is a "mud-pan" of 2½ cbm. capacity. D is a tank, holding 0.8 cbm., let into and level with the floor. F is a Körting's steam elevator. A wooden framework is placed close to the vessel B, for the workman to stand upon. Two iron sieves are suspended inside B by means of a chain which passes over a pulley above. For extracting samples with over 10 per cent. of insoluble matter, the apparatus shown in Fig. 2 is employed. A is a wrought-iron tank holding about 6 cbm., in which the liquid used for treating the ash is warmed by means of free steam from E. B is a dissolving-tank of 12 cbm. capacity, fitted with a tap L just above the bottom. In the vessel B is a perforated iron sieve H resting on well-burnt bricks. C is the "mud-extractor" of 9 cbm. capacity, fitted with two steam inlets. D is a tank, holding 0.8 cbm., fitted with its upper edge level with the floor. F is a steam elevator.

Fig. 1.

Fig. 2.

THE TREATMENT OF THE CRUDE RESIDUE OF BEETROOT MOLASSES.

The treatment of ashes containing up to 10 per cent. of insoluble matter is conducted as follows: The tank B (Fig. 1) is about two-thirds filled with water, which is then heated by means of steam to about 50° C. Crude ash is then dropped into the sieve until the solution has a density of about 30 B. Finally, the mixture is heated nearly to boiling, and subsequently allowed to settle for two days, when the clear lye is syphoned off and transferred to evaporating pans. A fresh portion of ash can then be

treated in B. After every two or three operations the slime collecting in B is run off through the tube at the bottom into C, where it is repeatedly extracted with water heated to boiling by free steam, until all soluble salts are removed. The weak lyes obtained are syphoned off into D, and from thence elevated into B, and employed to extract a fresh portion of crude ash. Samples containing over 10 per cent. of insoluble matter are treated as follows:—The false bottom of the vessel B (Fig. 2) is covered with a smooth layer of straw, hand-deep. The raw ash is evenly distributed over this filtering bed until the vessel is filled. Meanwhile, water is warmed in A to 50° C. and then sprinkled over the contents of B until the ash is completely covered. After 24 hours the solution, which has a density of 40°–42° B., is drawn off through L. The first portion, which is always turbid, is collected separately, whilst the clear portion of the lye is transferred to an evaporating pan. The tank B is again filled with hot water, which after five hours is tapped off, the operation being repeated until the extract has a density of only 2°–3° B. The mud from B is run into C, where it is boiled with water and steam to extract the remaining soluble matter. The weak lyes obtained are syphoned off into D and then elevated to A to be used instead of water for dissolving purposes.

The solutions obtained by the above processes are subsequently treated in precisely the same way. They are concentrated in an evaporating pan (1) up to a density of 40° B. at the boiling point, when the fire is somewhat slackened. After three to four hours, the clear lye is run into crystallising tanks which are made of wrought-iron, 3 m. x 4 m. x 50–60 cm. deep. It is well to construct the tanks with an inclined bottom. During the three to four hours that the hot solution remains in the evaporating pan (1) it deposits a heavy crystalline mud consisting chiefly of potassium sulphate. Once or twice weekly the precipitate is removed and washed with cold water, in a small iron box fitted with a sieve bottom, until the washings have a density of only 10°–13° B. The washings are returned to the pan (1) and again concentrated with fresh lye.

The liquid in the crystallising tanks is allowed to remain until it has cooled to 29° C. or at lowest 27° C., by which time the greater portion of the potassium chloride will have separated. Further cooling should be avoided, because it leads to the most undesirable crystallisation of a double carbonate mixed with potassium chloride. Therefore, as soon as the temperature reaches 29° C., the liquid is syphoned off and transferred to an evaporating pan (2). The crystals are washed with cold water until they contain at most only 1 per cent. of potassium carbonate, the washings being returned to the evaporating pan (1).

The potassium sulphate when dried has the following average composition:—

	Per Cent.
K ₂ SO ₄	92.22
K Cl	3.15
K ₂ CO ₃	2.34
H ₂ O.....	1.22
Insoluble and undetermined.....	1.07
	100.00

The dried potassium chloride consists of—

	Per Cent.
K Cl	89.14
K ₂ SO ₄	9.67
K ₂ CO ₃	0.91
Insoluble and undetermined.....	0.28
	100.00

The lye, almost freed from potassium chloride and sulphate is concentrated in pan (2) up to 50° B. Much soda separates during this operation, and must be continually chipped off the bottom of the pan with a sharp chisel in order to avoid burning of the metal. After concentration the liquid is allowed to remain at rest for one hour, so that the soda may settle. The liquid is then syphoned into an evaporating pan (2a) where it remains until it has cooled to 50° C., after which the liquid is transferred to a crystallising tank. The deposit formed in the pan (2a)

consists of potassium chloride and sulphate, and is again worked up in pan (1). The soda deposit from pan (2) is transferred as quickly as possible to a washing-tank provided with a perforated false bottom covered with coarse linen. Here it is washed with a hot solution of soda at 32°–34° B., and in order to prevent the mass setting it is necessary to stir it vigorously with a shovel for some time. Washing is continued until the filtrate has a density of about 38° B. The washings are added to pan (2). Meanwhile, the liquid in the crystallising tank deposits on cooling large crystals of a double carbonate of sodium and potassium, and the more thorough the cooling, the more complete is the separation of the double salt. The supernatant liquid is further concentrated in another pan (3) up to 52°–57° B. A further portion of soda separates at this stage, and is added to pan (2). When the lye has attained the desired concentration it is allowed to settle for one hour and transferred to a calcining furnace. The double salt from the crystallising pans is dissolved in lye freed from potassium sulphate and chloride, from which the bulk of the soda separates at the boiling temperature. The calcining-oven is of the usual form, and is most carefully constructed. The furnace being raised to a light red heat, the concentrated lye from the pan (3) is run in a thin stream on to the hearth, and heated until it assumes a pasty consistency. At this stage a crust begins to form, which must be broken at intervals, the lumps formed being raked towards the bridge of the furnace. Great care must be taken to prevent the crust being melted, as serious explosions might result from the molten mass coming in contact with the underlying lye. When the charge assumes a crumbly state, all except about 300 kilos. is raked close up to the wall of the furnace, opposite the fire bridge. The 300 kilos. are evenly spread over the floor of the oven and constantly raked about. The heat is then gradually raised until the mass of potash almost glows, but does not melt. The mass is then withdrawn and a fresh portion of the charge spread over the furnace, and so on. A single workman can calcine from 1250–1500 kilos. of potash in 10 hours. In most cases the potash is still, more or less, coloured. In order to refine it, it is redissolved in water up to a density of 52°–54° B., allowed to settle and again calcined. The composition of the potash depends on the concentration of the lye before calcination, as will be seen from the following analyses of different samples:—

	Strength of Lye.		
	52° B.	55° B.	57° B.
K ₂ CO ₃	81.0	90.0	92.3
Na ₂ CO ₃	12.0	3.3	2.4
K ₂ SO ₄	1.1	2.1	1.2
KCl	2.4	2.8	2.0
H ₂ O	2.5	0.4	0.6
Undetermined and insoluble.....	1.0	1.4	1.5
	100.0	100.0	100.0

In addition to the above, silicate and phosphate of potash are always present, in consequence of which the potash is unfit for clear-glass making. For certain purposes a hydrated potash is required. For this purpose a strong solution of refined potash is concentrated in a bright cast or wrought iron pan, until it is found by trial that the mass contains about 16–20 per cent. of water. If a wrought-iron pan be used, it must be formed from one piece.

A purer potash is prepared from the potassium sulphate and chloride obtained during the initial stages of the lye concentration, by the Leblanc process.

The soda from the evaporating pan (2) is converted into soda crystals by solution and crystallisation.—H. T. P.

Ammonium Pyrosulphate. A. Fock and K. Kluss. Ber. 23, 3119—3151.

ALMOST all ammonium salts are isomorphous with the corresponding potassium salts. Amongst the salts of the sulphur acids, however, remarkable exceptions occur. Thus, in the case of acid sulphates there is no certain indication of isomorphism.

The authors have shown (Ber. 22, 3096) that the thio-sulphates do not exhibit isomorphism. From Marignac's work, quoted in Eammelsberg's "Handbuch der kryst. Chem." similarity of crystalline form would seem not to exist in the case of the sulphites, but doubt seemed to exist owing to little being known of ammonium pyro-sulphite ($(\text{NH}_4)_2\text{S}_2\text{O}_5$). The authors have obtained it in the form of deliquescent crystals by passing sulphur dioxide into a well cooled strong solution of ammonia, and then concentrating over sulphuric acid. These crystals are not isomorphous with crystals of the corresponding potassium salt. Analysis of the crystals agreed sufficiently well with the formula to satisfy as to their composition.—T. L. B.

Sulphuric Acid Manufacture: The Chamber Process. A. Schertel. (Jahrb. Berg. u. Huttenw. Sachsen, 1890.) Zeits. f. angew. Chem. 1890, 639—646.

A SERIES of experiments carried out on chambers fed with sulphur dioxide, obtained in the roasting of blende, &c.

In a number of systems of chambers combined in the usual way analysis of chamber gases at different points gave results similar to those of Lunge and Naef (this Journal, 1884, 258 and 633). In the first third of the first chamber a perfect mixing of the gases throughout the section of the chamber is not always found.

The effect was tried of passing the gases in at both ends of the first chamber, the exit being in the middle at the top; the middle portion of the chamber in this way becomes better worked, and the process of sulphuric acid formation thus, from analyses of the gases, would seem to be more evenly distributed throughout the chamber. Increased proportional action of the first chamber was also obtained. The previous work of the author (see this Journal, 1889, 283) is also reiterated.

In order to see how far the possibility existed of economising space by the erection of small chambers instead of the present larger ones, the first chamber of one system was divided into three by two partitions, so arranged that the gases must pass through each subdivision either from bottom to top, or from top to bottom. This brought about considerable variation in the temperature of the various portions of the chamber, the middle portion having a temperature higher, by some 10 degrees, than the two end sections. The yield of acid increased, but so did also the loss of nitro.—T. L. B.

New Application for Calcium Plumbate. G. Kassner. Chem. Ind. 1890, 13, 392—393.

See under XXII., page 160.

The Ferrous Sulphate Manufacture in France. Chem. Ind. 1890, 13, 472—473.

Ferrous sulphate is now frequently used as a manure, and its manufacture, especially in France, has therefore increased considerably. It is chiefly manufactured from pyrites, which are oxidised by exposure to the air. A second technically important method of preparation is the direct use of old iron or iron cuttings, which are dissolved in sulphuric acid of 20—25 B, wooden vessels, lined with lead, being used for the purpose. A greater profit, however, is yielded by the use of acid residues from other manufactures, which can be obtained very cheap. Some factories in France produce in this way very large quantities of ferrous sulphate. Agriculture proves more and more the great importance of this manure for the assimilation of the potash, contained in the strates of the soil. Its price at present is 4 to 6 francs per 100 kilos.—H. S.

Manufacture of Acid-proof Slabs for Glover-towers. Thonind. Zeit. 1890, 14, 642.

It is preferable to use materials rich in silica for stones which are to resist chemical actions. If clay free from iron cannot be obtained, a suitable mixture is 25—30 parts of felspar, an equal quantity of rich clay and 40—50 parts of quartz. The mass must not contract too much on firing. The following mixture may be advantageously used for glazing: 54 parts of quartz, 84 parts of felspar, 35 parts of levigated chalk, and 36 parts of kaolin. The ingredients are moistened and well ground together before use.—A. R.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

On the Application of Mesur's and Nouel's Pyrometer in the Earthenware Trade. H. Hecht. Thonind. Zeit. 1890, 14, 575.

THE author has experimented with this pyrometer, which is a kind of polarisation apparatus consisting of two Nicol's prisms as polariser and analyser, between which is a quartz. He finds that at the high temperatures used in earthenware manufacture, a difference of 100° C. make very little difference of reading on the instrument, and furthermore, the instrument is affected by the inevitable presence of the flame of the furnace itself, instead of by the heated body only, so that the author concludes that this form of pyrometer is not suitable for the earthenware manufacture.

—T. L. B.

Oberjama Pottery Clay. H. Hecht. Thonind. Zeit. 1890, 14, 592.

THE medium class of fire-clay is peculiar in that the sand contained therein is in such a fine state that washing alters the composition but slightly, as shown by the accompanying analyses:—

	Crude Clay.	Washed Clay (54.3 per cent.).
$\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2 \cdot 2\text{H}_2\text{O}$	30.55	37.48
Quartz	66.61	59.61
Felspar	2.84	2.91

This material from its character and composition and from the fact that it gives a pure white melt with felspar (ferrie oxide 0.55 per cent.) may be directly used as earthenware mass.—T. L. B.

Enamels for Iron and other Metals. Petrik. Monit. de la céramique et de la Verrerie, 1890, 21, 199.

IN case the enamel leaves the iron or if the surface of the iron should become curved, that is to say, if the contraction of the enamel on cooling be less than that of the metal, then according to the author the following points must be attended to: Either (a) the percentage of silica must be increased, or (b) part of the boric acid must be replaced by silica, or (c) in the case of enamels containing lead a portion of the oxide of lead must be replaced by alkali or alkaline earth, or (d) part of the alkaline earths must be replaced by alkali, or (e) the quantity of alkali must be increased, and the boric acid decreased, or (f) part of the oxide of tin may have bone ash substituted for it.

The composition is given of a number of satisfactory enamels.—T. L. B.

The Production of High-Temperature Blue on Porcelain.
C. Lanth. Le Manufacture de Sèvres, 1879—1887.

THE production of high temperature blue on porcelain is carried out at Sèvres as follows:—15 parts of black oxide of cobalt are ground up with 85 parts of pegmatite, and the mixture after being roasted painted on to the glaze of the fired porcelain. The pegmatite used contains 8·73 per cent. of alumina, 26·49 per cent. of quartz, and 64·58 per cent. of felspar, and is obtained from St. Yrieix la Perche, near Limoges. When the colour is put on underneath the glaze or on to the porcelain during cooling, the results are less satisfactory. After painting, the article is fired, when the colouring mixture soaks into the glaze and gives a beautiful blue colouration. During this burning the glaze is especially apt to boil up, a circumstance which cannot be overcome by a second firing. The cause of this the author has shown to be on the one hand the presence of reducing gases at the end of the firing, and on the other hand to there being too little draught when counter currents form, which give rise to an accumulation of gas and thus prevent complete combustion.—C. A. K.

PATENTS.

Improvements in or Connected with Apparatus or Appliances for Polishing Glass. V. Malevez, Courcelles, Belgium. Eng. Pat. 20,014, December 12, 1889. 6d.

A RING or frame actuated by a driving shaft is furnished with small disc polishers working on spindles. These polishers, besides the motion imparted to them by the revolving frame, acquire an individual motion of their own. If desired, however, they can be held in one position by means of a cotter passing through the collar of the polisher and spindle.—S. G. R.

Improvements in Machinery for Rolling Glass. Chance Bros. and Co., Limited, and E. F. Chance, West Smithwick. Eng. Pat. 785, January 15, 1890. 8d.

THE molten glass after passing downwards over an inclined plate through a pair of primary rolls is carried on to another inclined plate and thence to a pair of secondary rolls. The axes of these are horizontal, but are not vertically placed one above the other, their plane, however, being at right angles to that of the feeding or inclined plate. The secondary rolls rotate at a higher rate of speed than the primary, and may be impressed with a design or pattern which is then communicated to the still plastic glass sheet in its passage between them. The specification is illustrated by a drawing.—S. G. R.

Improvements in Plate and Rolled Plate Glass Annealing Kilns and Machinery. W. W. Pilkington, St. Helens. Eng. Pat. 927, January 18, 1890. 8d.

THE annealing kiln is built in the shape of an **L**, the glass being passed in at the one end, and when annealed pushed or drawn out through the other. The kilns are provided with gas and air nozzles, and also with baffle arches, in order more easily and effectually to control the temperature. The plates are moved forwards by means of rods fitted with studs, and suitably geared, which catch in the rear end of each plate. The plates are then allowed to cool in chambers, placed at the delivery end of the kiln, and which are alternately in use.—S. G. R.

Process for Producing Opalescent Glass from a Glass Mixture containing Silico-fluorides of Alkalies or Compounds thereof. C. Huelser, London. From J. Kempner, Goerlitz, Germany. Eng. Pat. 2626, February 18, 1890. 4d.

THE patentee adds a small quantity of the silico-fluorides of potassium or sodium to the batch. This addition gives an opalescent glass even when added in small quantity. Fluorides alone, including cryolite, unless in much larger excess, produce only a clear white glass.—S. G. R.

Improvements in the Manufacture of Fibrous Material from Slag or other Vitreous Substance, and in the Apparatus used in such Manufacture. C. Wood, Middlesborough. Eng. Pat. 5847, April 17, 1890. 8d.

THE filaments and heavy particles produced by the action of a blast of steam or air upon the molten slag are carried forward through a tube terminating in a bell mouth into a chamber, where they impinge upon the vertical projecting angle of an upright screen. The heavier dross falls first into a chamber placed beneath, while the lighter glassy-wool, deflected on either side towards the sides of the chamber, pass on and come in contact with two sets of vertical boards inclined in such a way that both those to the right and left of the screen slant inwards towards the centre of the chamber, thus slanting as regards themselves in opposite directions. The residual heavy particles are here trapped and the wool passes inwards into the chamber, the heavier fibres falling first and nearer to the partition boards.—S. G. R.

A Method of Cutting Glass Tubes and Apparatus employed therein. H. Becker, Barmen, Germany. Eng. Pat. 12,536, August 11, 1890. 8d.

AN iron rotating disc is pressed against the glass which is to be cut, the latter being also caused to slowly rotate in the same direction as the disc, an even cut being thereby effected. The pointed very hot flame of a gas jet is directed upon each of the shallow grooves, the glass then breaking smoothly across at each of these places and leaving no irregularities whatever. The specification is illustrated by drawings.—S. G. R.

Improvements in Pottery Kilns. F. C. Roberts, Philadelphia, U.S.A. Eng. Pat. 13,436, August 26, 1890. 8d.

IN the centre of the kiln, which is dome-shaped, is a down-take flue fitted with a circular cover with radial openings through which the products of combustion pass away to the regenerators and thence to the chimney. At equi-distances round the interior are placed air and gas ports in groups of three, the gas ports occupying the central position. Between the down-take and the ports are the supports upon which the articles to be fired are placed. By a suitable arrangement of valves the ordinary reversal of the currents of gas and air and of the hot waste products of combustion is obtained, but this reversal takes place outside the kiln, so that the currents within always flow in the same direction. The patentee claims this modification as being essential, the kiln otherwise becoming cooled down at the various inlets, an irregular and defective product being the result. The specification is illustrated by three sheets of drawings.—S. G. R.

Improvements in Apparatus for the Manufacture of Glass-Ware. J. T. King, Liverpool. From E. and J. A. Jones, Pittsburg, U.S.A. Eng. Pat. 14,983, September 23, 1890. 8d.

A SUITABLE bed carried on pillars supports a mould, sliding into which is the "former." This having been filled with molten glass is raised to its position within the mould. A plunger, formed of a hollow tube, terminating in a rounded head carried on a pair of stout spiral springs within the hollow tube is now strongly depressed, whereby the glass is forced into the shape of the mould. The "former" is now lowered, leaving the glass behind and the orifice closed by a tightly fitting plate, the upper being also closed by a plate carried on the plunger. Compressed air is then admitted down the hollow plunger, and by slightly raising this can escape by the opening between the movable head and the body of the plunger into the cavity of the mould, thereby blowing the glass to the full size of the mould. The specification is illustrated.—S. G. R.

Improvements in Machinery for Manufacturing Cups and other Articles in Pottery-Ware. W. Boulton, Burslem. Eng. Pat. 16,112, October 10, 1890. 8d.

A SERIES of spindles are furnished with external or internal shaping profiles carried on a counter-balanced jolly-arm common to the whole series. There is a further arrangement so that two or more articles can be made simultaneously. In connection also is an automatic table working both vertically and horizontally. In its horizontal movement it brings the moulds filled with clay and then removes the articles when formed, whilst when working vertically the moulds are placed or removed from their position on the jigger-heads. Automatic scrapers or apparatus for removing the scrap clay projecting from the top of the moulds are also added.

—S. G. R.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

The Practical Application of Magnesia Cement.
C. O. Weber.

See pages 111—114.

Comparative Examination of Puzzolana, Portland and Roman Cements. Boehme. Mitt. Konig. tech. Versuchs. 1890, 256—269.

IN order to ascertain whether a reliable examination and comparison of different sorts of cement is practically possible, a series of Puzzolana and Roman cements were tested in the same way as Portland cements are usually tested in Germany. The tests were made in accordance with the rules laid down officially (see this Journal, 1888, 107—109), by which it is required that samples of mortar, consisting of one part of cement and three parts of sand (gravimetrically apportioned) must have at least a tensile strength of 16 kilos, and a strength of compression of 160 kilos, per sq. cm., respectively, after the samples have been hardened one day in the air, and 27 subsequent days under water.

The examination showed that the weights of equal volumes of the different kinds of cement varied considerably, so that if one volume of cement and three volumes of sand (the so-called "normal-sand" was always used) were mixed under similar conditions, different gravimetric results were obtained. In practice this volumetric mixture is the usual one employed. The different mortars which were hardened either entirely in the air or one day in the air, and then under water, were tested for their tensile strength and strength of compression, and for their powers of resistance to grinding. The results proved that the mortars consisting volumetrically of one part of cement and three parts of sand, were inferior to other mortars mixed gravimetrically 1:3. As regards Roman and Puzzolana cements, the average results were below the above-mentioned official standard, and varied so much that a method like that used for the testing of Portland cement, cannot be employed for Roman and Puzzolana cements. If in practice the cement and sand were mixed gravimetrically, instead of volumetrically, the results would be better and more uniform. (Compare this Journal, 1886, 188—199).

—H. S.

Hydraulic Cements. Candlot. Bull. Soc. d'Encouragement, 1890, 682—716.

THE paper, which is long and accompanied by numerous voluminous tables, has been submitted to the judgment of H. le Chatelier, who reports as follows:—

The object of the paper is to elucidate the causes of the action of the sea upon works executed in hydraulic cement. Putting aside for the moment the influence of porosity of the materials used as too obvious to need elaboration, the

present research has been concerned with such other disintegrating agencies which have hitherto been matter rather for speculation than knowledge. Candlot has already shown (this Journal, 1889, 544) that of the three salts present in sea-water in notable quantity—sodium chloride, magnesium chloride, and magnesium sulphate—sodium chloride is inert, and the magnesium salts begin to act only after they have produced corresponding calcium salts by double decomposition with the lime of the cement. With regard to one of them, calcium chloride, it has been demonstrated (this Journal, 1890, 72) that dilute solutions, e.g., 20 grms. per litre, retard setting in the same way that sea-water does while strong solutions, e.g., 300 grms. per litre, increase the speed of setting considerably. In the present memoir Candlot has arrived at what appear to be the reasons for this seeming anomaly: weak solutions of calcium chloride hinder the solution of the alumina of the calcium aluminates chiefly concerned in the setting as opposed to hardening of hydraulic cements probably decomposing it and forming calcium oxychloride with its lime; strong solutions of calcium chloride, however, increase the solubility of both aluminates and ferrites, a solution containing 300 grms. of calcium chloride per litre dissolving as much as 25 grms. of alumina per litre, while pure water will only dissolve 1 gm.; this large increase of solubility is due to the formation of a calcium chloro-derivative which being stable only in presence of a strong solution of calcium chloride has not yet been satisfactorily analysed. These interesting and wholly novel facts are not without analogies in chemistry. For instance, lead chloride, which is only slightly soluble in water, is completely insoluble in dilute hydrochloric acid, but is readily soluble when strong acid is used. A possible application of these results exists, viz., the construction of a method for detecting free lime in hydraulic cement; cement containing free lime sets immediately when gauged with a strong solution of calcium chloride, while in the contrary case the setting is slow. Candlot has also examined the action of calcium sulphate on hydraulic cements. The formation of a perfectly definite and well-crystallised salt—

has been proved. This salt is insoluble in lime water, but is decomposed by it when the proportion of lime falls below about 0.2 grms. per litre, and *a fortiori* by pure water.

The tendency of calcium chloride and sulphate formed by double decomposition from the magnesium salts present in sea water, to act on the constituents of the cement—yielding compounds of this description, whose repeated crystallisation and decomposition gradually disintegrate the cement, throws a good deal of light on the failures of marine work that have occurred.—B. B.

Corrosion of Lead and Zinc in Contact with Cement.

Seeger. Thonind. Zeit. 1890, 14, 545.

THE fact that lead and zinc corrode when in contact with cement is here said to be due to the alkalinity of the cement, and to the sulphates contained in the bricks. The solution of these constituents is effected by the moisture deposited on the pipes or sheets (see also this Journal, 1890, 1037).

—T. L. B.

PATENTS.

Improvements in the Treatment and Utilisation of Peat, Sawdust, and other Fibrous and Vegetable Materials and Substances. R. Stone, London. Eng. Pat. 795, January 15, 1890. 4d.

THE inventor mixes silicate of soda or siliceous compounds, in solution or otherwise, with the peat, &c. The mixture may consist of silicate of soda, in solution, 15 parts, glue 5 parts, and the materials to be cemented, 80 parts. The composition is run or pressed into moulds or dyes of any required form, or rolled out into sheets, slabs, or other suitable forms.—E. G. C.

Improvements in or Appertaining to the Manufacture of certain kinds of Bricks and Fireclay Substitutes. C. H. Edwards, Liverpool. Eng. Pat. 2371, February 13, 1890. 6d.

WASTE sand from plate-glass works containing about 75 per cent. of silica, 20 per cent. of ground glass, 2 per cent. of iron, and 3 per cent. of the chlorides of sodium, potassium or magnesium, or of emery, is mixed with a non-ferruginous clay or ground aluminous shale, such as is commonly found in contiguity with coal seams, in proportions ranging from 9 of sand with 1 of clay to 1 of sand with 1 of clay, the sand being dried previous to use and the clay ground in its natural, dry, or semi-dry state with it. Should the clay be too dry, water may be added. 20—25 per cent. of ground old firebrick may be added. The mixture is made into bricks and burnt in the ordinary way. When somewhat wet materials are used they can be mixed in that condition, preferably, in an open mixer.

The advantages claimed are, first, that the bricks are produced from a hitherto waste material, and that they are glazed on account of the glass present in the raw material, that they are hard, non-conducting to heat, and refractory enough for furnace use.—B. B.

Improvements in the Manufacture of Cement and in Apparatus for Use in the said Manufacture. W. Joy, Snodland. Eng. Pat. 2896, February 22, 1890. 8d.

Two improvements are claimed. The first is the introduction of steam into cement kilns during the burning of the charge, the steam being generated either in separate boilers or in pipes or other suitable apparatus arranged round the kiln to receive heat from it. The steam, before its introduction into the kiln, may be passed through incandescent coke or other fuel.

The second is a method for drying slurry by means of the waste heat of the kilns. It consists essentially of long chambers level with the top of the kiln, through which the hot products of combustion are caused to pass systematically, drying the slurry in their passage.—B. B.

Improved System of Continuous-acting Kilns. G. Appiani, Treviso, Italy. Eng. Pat. 2941, February 24, 1890. 8d.

The patentee has devised a system of heating continuous-acting kilns, also applicable to kilns fired intermittently, which essentially consists in constructing the kilns with retorts within them in which the fuel for heating them is gasified before use, the gaseous products passing from the retort inserted in the kiln that heats it to the next kiln where they burn, and in their turn serve to heat the internal retort and gasify a fresh supply of fuel. Where the demand for the coke or other residual material is not sufficient to justify the production of the full amount possible by this arrangement, the method of heating first described can be supplemented by burning some of it in the ordinary way in the kiln. It is not necessary that the retorts inserted in the kilns should be actual structures; they may be spaces in the mass of the material to be burnt, constituting what are in effect retorts.—B. B.

An Improved Method of Hardening and Preparing Soft Porous Stone for Enamelling and other Purposes. W. T. Sier, Newport. Eng. Pat. 3413, March 4, 1890. 4d.

SOFT porous oolite stones are boiled in a bath of "silica or flint" of a "registered strength 1175" for eight hours under pressure, after which they are "placed in a drying stove registered heat 200 F." The material is then boiled with ground alabaster and lime water, when it is ready to receive the enamel and to be used for "chimney pieces and other architectural work." Soaking for eight days may be substituted for boiling, but the latter is preferable. The dried stone is then coated with "alabastine" or distemper, and is then fit for enamelling. For stones exposed to the weather the boiling with alabaster and lime water, after they have been worked to shape, suffices as a "preventative for salting."—B. B.

Improvements in Plastering Compositions. W. A. Robinson and J. Y. Terry, Syracuse, U.S.A. Eng. Pat. 15,678, October 3, 1890. 4d.

THE invention consists in "mixing and commingling" sawdust ("previously saturated in a solution of lime, alum, white lead, and water"), sand, hair, plaster of Paris, glue and water.—E. G. C.

An Improved Method of and Kiln for Burning Bricks. P. Crean, Belfast. Eng. Pat. 16,231, October 13, 1890. 6d.

THE furnaces are kept open until the bricks are "steamed," and then closed, the heat being maintained by the introduction of small quantities of slack or coal dust through openings provided in the kiln above the furnaces.—E. G. C.

A New or Improved Manufacture of Artificial Stone or Composition and Building Blocks and other Articles thereof. F. Jurschina and R. R. v. Gunesch, Vienna, Austria. Eng. Pat. 18,468, November 15, 1890. 4d.

ONE hundred parts by weight of ground quartz-sand or flint gravel, from 1—4 parts of Tripoli, and from 1—6 parts of Portland cement, are made into a plastic mass with soda water-glass at 25°—38° B. and pressed or cast into moulds. The proportions may be varied. The material is said to be useful for making building-blocks, paving-slabs, grindstones, and fireproof and acid-proof vessels and linings. Where hardness rather than sharpness in the finished goods is required, the materials after being dried are burned "at a glowing heat and allowed to cool slowly."—B. B.

The Cyanide Process for Extracting Gold. B. Blount.

See pages 95—96.

Preparation of Chromium. E. Glatzel. Ber. 23, 3127—3130.

POTASSIUM chromic chloride is reduced by magnesium in presence of potassium chloride. 100 grms. of potassium bichromate are dissolved in as little water as possible, and to the solution are added 400 cc. of hydrochloric acid (sp. gr. 1.124) and then 100 c.c. of 80 per cent. alcohol. Potassium chromic chloride is obtained according to the equation—

To the solution so obtained, 160 grms. of potassium chloride are added, and after filtration the whole is evaporated to dryness, and further heated. Green particles are removed, and the mass is then powdered and mixed with 50 grms. of magnesium cuttings; that is, about double the quantity theoretically necessary. The mixture is raised to a red heat for half an hour in a covered Hessian crucible. On cooling, the crucible is broken, the dark grey mass is freed from particles of chromic oxide, and is then thrown into water. By decantation the potassium chloride and magnesium chloride are got rid of, and then the excess of magnesium and the magnesia are removed by the aid of dilute nitric acid. The chromium is finally dried on the water-bath. It is obtained in such a finely-divided state that filtration cannot be used in the foregoing purification processes.

As obtained, the chromium consists of microscopic crystals, almost white. Rubbed in an agate mortar, it shows metallic lustre. Its specific gravity at 16° C. is 6.7284 (Wöhler found 6.81 at 25°; Bunsen, 6.7). A magnet has no effect on the metal.—T. L. B.

New Metallurgical Process for Cobalt and Nickel Ores.
Chem. Zeit. **14**, 1475.

THE ores are first melted in a reverberatory furnace to a matte containing 6–12 per cent. of cobalt, which is then roasted. The product is next treated with chloride of iron in muffles, when the following changes take place:—

The reaction is ended after about two hours, when the resulting mass is lixiviated with water in wooden vessels provided with a false bottom. The cobalt and nickel, together with a trace of iron, go into solution, which solution can be concentrated simply or worked up to oxide.

The extra cost of this new process, which is patented by W. Schöneis, is small, since the iron chloride solution is a waste product in the wet copper process, and the resulting oxide of iron is a marketable product.—C. A. K.

Alloys of Sodium and Lead. W. H. Greene and W. H. Wahl. J. Franklin Inst., 1890, **100**, 483–484.

THE alloys examined contained from 3 to 31 per cent. of sodium, and were prepared by the direct union of the two metals. They were all brittle and crystalline, and all decomposed water. The brittleness and oxidisability increased with the percentage of sodium. The alloy richest in sodium was greenish in colour, but instantly blackened on exposure to air. Special examination was made of the alloys having the compositions corresponding to the formula Na_2Pb_2 , Na_3Pb , and Na_4Pb . The densities of these alloys were determined in aniline and found to be much higher than the densities calculated on the supposition that they were simply mixtures. The following table shows the composition and density of each:—

	Na_2Pb_2	Na_3Pb	Na_4Pb
Sodium per cent., theoretical	10	18.18	30.8
Sodium per cent., found	10	19.50	31.7
Density calculated	5.6	3.7	2.7
Density found	6.93	4.61	3.81

A New Modification of the Open-Hearth Steel Process.
F. Kupelwieser. Eng. and Mining J. **50**, 575.

THE author recently published some calculations showing that by running the molten metal direct from the blast furnace into the open hearth furnace a saving in fuel might be effected to the extent of 3 cwt. per ton of metal. This plan was adopted with three furnaces at Witkowitz, where owing to local difficulties of transfer an empty Bessemer converter was used as an intermediate reservoir. Subsequently the process was modified by blowing the blast-furnace metal in this converter for two minutes, whereby the bulk of the silicon and manganese was removed and the metal rendered more suitable for the basic-lined furnace. The amount of heat developed by this short blow is calculated at 67,000 calories per ton of 1,000 kilos. About one-half of this is lost by radiation, and as there is a further diminution on account of the double transfer to and from the converter, the loss and gain of heat about counterbalance one another. The charges consist of 50 per cent. of blast-furnace iron, 10 per cent. of scrap, together with the necessary amount of ore and some lime. The work is rapid, and the three furnaces work from 15 to 18 charges or an average of 17 per 24 hours. The fuel used only amounts to between 10 and 12 per cent. of the weight of ingot produced.—A. W.

Zinc from Flue Dust of Zinc Furnaces. E. Jensch. Zeits. d. obersehles. berg. u. hüttenm. Ver. 1890, **29**, 355.

OWING to the extensive loss of zinc in the flue dust, this is smelted with calamine or blende. In an experimental smelt of the dust the percentage of iron in the zinc was 0.71, whereas the zinc obtained from calamine or blende contains only 0.024 per cent. This is due partly to the chlorine of the flue dust, but chiefly to its finely divided condition; the draught carries over the fine oxides of iron into the zinc. Whether an alloy of zinc and iron is formed, or whether merely a mixing of the oxides of iron with the zinc takes place is not known.—T. L. B.

On Blast Furnace Slags and the Fusibility of Silicates (concluded). A. J. Rossi. J. Amer. Chem. Soc. 1890, **12**, 307–339. (See this Journal, 1890, 1039).

THE author points out the fact that all silicates, however complex their composition, may be reduced to five types:—

Acid silicates, of the formula . . .	$\text{RO}, 2 \text{SiO}_2$
Sesquiacid „ „	$2 \text{RO}, 3 \text{SiO}_2$
Neutral „ „	RO, SiO_2
Sesquibasic „ „	$3 \text{RO}, 2 \text{SiO}_2$
Bibasic „ „	$2 \text{RO}, \text{SiO}_2$
Tribasic „ „	$3 \text{RO}, \text{SiO}_2$

In order to ascertain in a given case to which type a silicate belongs, all the bases, whether of the form R_2O , RO , or R_2O_3 , are replaced in the formula by an *equivalent* quantity of lime, CaO ; the transformed formula approaches in all cases to one of the above-mentioned types. The author shows by a number of examples, taken from actual practice and quoted in detail, that the *quality of iron produced depends rather on the type of the slag produced* than on its special qualitative composition.

In the one case of *acid* slag, the iron was grey.

Out of five cases of *neutral* slags, the iron was in four cases white, and in one, mottled.

Out of 32 cases of *sesquibasic* slag, the iron was in 12 cases white, 3 cases white and mottled, 2 cases light grey and mottled, and 11 cases grey, the shade being mostly light.

Out of 30 cases of *bibasic* slag, the iron in 3 cases was white, in 2 grey and mottled grey, and in 25 cases grey. Graphitic No. 1, No. 2^{ss}, No. 2^s, and No. 2, the darker shades corresponding most generally to slag approaching nearly to the typical bibasic slag. The three cases of white iron were due to chromium present in the pig.

In the two cases of *tribasic* slag the iron was No. 1 graphitic iron.

Hence it follows that with an acid slag a grey iron may be expected; with neutral slag, a white or mottled iron; with sesquibasic slag light grey or mottled, only under special conditions white iron, and this pig containing less silicon being specially suitable for puddling; with bibasic slag a grey pig varying from the darkest shade to No. 2, No. 1, No. 2^{ss}, and kish cinders. With a tribasic slag the iron is invariably a No. 1 iron, Scotch grey.

The fusibility of the slag depends on their type and is given as follows:—

Acid.—Fusible.

Sesquiacid.—Moderately fusible.

Neutral.—Very fusible.

Sesquibasic.—Very fusible, but less than preceding one.

Bibasic.—Fusible.

Tribasic.—Fusible, but less than preceding one.

The higher grades of iron containing most silicon and total carbon correspond to higher temperatures in a furnace and are accompanied by the more basic slags. Blast-furnace practice therefore corroborates the observation that neutral silicates are more fusible than either more basic or more acid ones.

The author works out in detail an example of the charges requisite to yield a given type of slag with a given sample of ore and coal, and draws attention to the necessity of taking into consideration the *ash* in the case of inferior coals and anthracite; in some coals this may amount to 15 per cent.

Actual analysis shows that the slag produced agrees very closely with the product for which the charges were calculated. The failure to obtain, within certain limits, a desired grade of iron with a given slag, is a useful indication to the iron-master of abnormal temperature, blast pressure, &c., or of an unnoticed change in the composition of the ore.

Numerous analyses of slags are inserted in the body of the original paper.—P. J. H.

Outbursts of Gas in Metalliferous Mines. B. H. Brough.
School of Mines Quarterly, **12**, 13—22.

THE author gives an account of a number of cases in which gas has been liberated in metalliferous mines and in some of which serious explosions have occurred. He shows that these outbursts of gas are not always due to the same cause, and he gives the following explanation to account for the formation of the gas in the various cases described:—

(1.) The decomposition, in a mine, of timber in contact with water or moist air may produce fire-damp which would accumulate in cavities that are ultimately broken into. (2.) In iron mines where the iron is not entirely in the state of peroxide, water might be slowly decomposed and hydrogen produced. (3.) Fire-damp may be liberated from beds beneath the ore-deposit and find its way through fissures into the workings, the gas being given off from rocks enclosing bitumen in the same way as the natural gas of the United States and other countries. At some of the Derbyshire mines, the gas is derived from the Yoredale shales which are of a bituminous character. (4.) Fire-damp may be produced from the decomposition of organic matter in the same way as the hydrocarbon met with in salt mines. (5.) In some cases explosions have been caused by outbursts of sulphuretted hydrogen produced by the action of

acid waters on pyrites ore. (6.) The outbursts of carbon dioxide met with at Foxdale, Freiberg, and Massa Maritima, may have been caused by the action of acid water, produced by the oxidation of pyrites, on limestones and other metalliferous carbonates.—A. K. M.

The Precipitation of Metallic Sulphides by Natural Gas.
J. F. Kemp. Eng. and Mining J. 1890, **50**, 689.

THE investigations of many distinguished observers tend to indicate that there are two possible and probable varieties of natural gas and petroleum. The two differ genetically, the one having probably been derived from animal organisms, the other from vegetable. The hypotheses of origin are numerous, and will be found cited or abstracted in S. F. Peckham's Report on Petroleum in Vol. X. of the Tenth Census, and fully set forth and discussed by E. Orton in the Geology of Ohio, **6**, 60—83. Suffice it to say that the oil and gas in sandstone receptacles, but mostly originating from bituminous shales, especially as found in Pennsylvania, have been generally attributed to an original vegetable tissue; while, on the other hand, the oil and gas from limestone have been generally referred to animal tissue. The latter have disagreeable odours (Enniskillen, Canada; Findlay and Lima, Ohio), and are marked by the presence of sulphur compounds. Their importance and general distribution have been of later development. It is not here intimated that the vegetable remains lack sulphur. The general presence of this element in coals, and in illuminating gas derived from coal, proves the contrary, but as shown in the accompanying table, it is a curious fact that in the published analyses of natural gas from Pennsylvania and other sandstones, sulphur does not appear, while in those from Ohio and Indiana limestones it does.

⁵ E. W. Morley. Orton, l. c., p. 416.

⁶ C. C. Howard. Mineral Resources U.S. 1888, 490. From Trenton limestone.

⁷ Quoted by Orton, l. c., p. 137.

Thus the sulphuretted hydrogen in the limestone gas runs from 0.15 to 0.20 per cent. This may have an important bearing on the origin of ore deposits, as it indicates the form assumed by much of the sulphurous matter in limestones. Experience has shown that natural gas collects especially at the summits of anticlinals which may be very gentle, and along arrested anticlinals or monoclinals (see Orton, *Geol. Ohio*, 6). When in large quantities, it favours porous or fissured limestone which may have been brought into this condition by dolomitisation. In Ohio almost all the limestones in the State are more or less petroliferous, the Trenton being the principal productive source. The Emiskillen field, in Canada, has been referred by Hunt to the corniferous, and the oily Niagara limestone of Chicago is familiar to all.

A still wider geological range could be easily substantiated, but the above will serve to illustrate the frequent presence of oil and gas in limestone. With such imprisoned sulphurous material, even though dispersed, a precipitating agent is at hand for any of the common metals that might circulate through the rock in solution. The precipitating agent is especially abundant in the fissured and porous portions, which are likewise most open to circulations. C. C. Howard states that in 100 cub. ft. of Findlay gas there are 125.8 grains of sulphur (*Geol. Ohio*, 6, 137). If the calculations be made for the famous Karg well, which produced approximately 12,000,000 cub. ft. of gas daily, it will be found that it is equivalent to 2,630 lb. of sulphur. Reducing this to the corresponding amounts of pyrites, blende, and galena, it is equivalent to 1,915 lb., 8,733 lb., and 19,552 lb. respectively. It is understood, of course, that these figures are only illustrative, but they show forcibly the potential precipitating power which may be stored up under favourable conditions. The Karg well is only one among numerous productive wells in a restricted territory. In Indiana (*Mineral Resources*, 1888, 502), in an estimated area of 2,525 sq. miles, the daily production of gas is thought to be 700,000,000 cub. ft. of a sulphur content, as shown by the table, somewhat less than in the above calculation.

It is reasonable to infer that, in other districts where metalliferous circulations have passed through limestones, similar gases have aided in their precipitation. Where masses of galena, pyrites, blende, or other sulphides are found disseminated through limestones, sulphurous gases and oils may have played an important rôle in their formation. Except as the result of special local study, caution should be observed in citing illustrations: with due reservation, therefore, it is merely suggested that the Saucun Valley blende deposits near Bethlehem, Pa., exhibit the sulphide filling innumerable cracks and small fissures in magnesian limestone along the shattered crest of an anticline (Cleve, F. L. *Mineral Resources*, 1882, 361. Drinker, H. S. *On the Mines and Works of the Lehigh Zinc Co.* Trans. Min. Eng. 1, 67. Hall, C. E. Rept. D3., 2nd *Geol. Surv.*, Penn., 239). The blende deposits of south-west Missouri have abundant bitumen (inspired petroleum?) associated with them (Schmidt and Leonhard. *Mo. Geol. Surv.*, 1874, 384), which is at least suggestive.

Light may be thrown on the chemistry of certain phases of the replacement process which figures so largely in the modern explanations of ores. Lead, for example, circulating as sulphate or chloride in solution would be precipitated as sulphide by sulphurous gas or oil. The resulting sulphuric or hydrochloric acid formed by the reaction would at once be taken by the calcium carbonate present, which would be removed as sulphate or chloride. The same is true of zinc or iron, for although they are precipitated by sulphuretted hydrogen only in alkaline solutions, calcium carbonate is at hand to neutralise at once the free acid resulting from the reaction. In this way a molecular replacement might easily result.

The filling of fissure veins in limestone as well as other rocks is usually attributed to the evaporation of standing solutions, or to the lowering of the temperature and pressure of solutions of metallic sulphides in alkaline carbonates or alkaline sulphides, or both, as they approach the surface. The evolution of sulphurous gases through such fissures would also cause precipitation in rising or standing solutions, and Chamberlain has, indeed, cited such a method for the

gash veins of Wisconsin (Chamberlain, T. C., *Wisc. Geol. Surv.* 4, 367).

It would be interesting to note in particular instances whether bodies of disseminated ores may not follow in their distribution the laws now fairly well understood for natural gas and oil, for if they do, some hints would be afforded for prospecting.

PATENTS.

Improvements in the Treatment of Tin Refuse or Slag. T. Teagne, Devonan. Eng. Pat. 19,687, December 7, 1889. 4d.

THE natural alloys of tin and other metals resulting from the refining of smelted tin in the ordinary manufacturing process, and known as hard-head, are melted with copper, whereby an exceedingly hard bronze is produced, suitable for machine bearings, wire, &c. A good proportion of hard-head is 10 per cent.—H. K. T.

Improvements in Galvanising Apparatus. J. Lysaght, Bristol. Eng. Pat. 20,587, December 21, 1889. 6d.

THE object of this patent is to facilitate the withdrawal of the sheets, &c., from the galvanising bath and to automatically cleanse them, reducing the use of hand labour to a minimum by mechanical appliances. The sheets are raised by a pair of rolls working in the molten metal, and are brought upwards against a set of revolving discs working on a horizontal shaft. These discs, which have sharp points projecting from them, deflect the sheets over other discs with blunt agate points, by which they are carried forward to a pair of grooved rolls, which in turn force them through a pair of cylindrical revolving brushes against which jets of water are directed. The sheets are then passed through a pair of rubber rolls similar to those of a wringing machine, and finally through a heated chamber to dry them. Five drawings are given.—A. W.

Improvements in or connected with the Manufacture or Production of Aluminium. W. White, Cheshunt. Eng. Pat. 859, January 16, 1890. 4d.

IN the manufacture of aluminium practically pure fluoride of aluminium is used instead of cryolite, which contains impurities. The fluoride is prepared by adding hydrofluoric acid to aluminium hydrate and evaporating to dryness. It is then heated with sodium or potassium or a mixture of these, keeping an excess of aluminium fluoride present as it helps by combining with the sodium fluoride formed to produce a more suitable flux for the metal. The flux is afterwards treated with sulphuric acid to produce hydrofluoric acid, which is again utilised for dissolving a fresh quantity of aluminium hydrate.—A. W.

Improvements in and connected with the Recovery of Zinc from Galvanised Iron and Steel. H. Grimshaw, Manchester. Eng. Pat. 1053, January 21, 1890. 4d.

THIS invention is for the purpose of recovering zinc from galvanised iron and steel without injury to the iron or steel. The coated metal is immersed in a solution of sulphate, nitrate or chloride of zinc containing a small quantity of the free acid, and maintained at a temperature of 200° F. Fresh acid is added from time to time and the saturated solutions of zinc salts are drawn off and the zinc recovered by known means.—H. K. T.

Improvements in the Reduction of Metallic Ores and in Apparatus therefor. J. T. King, Liverpool. From C. Adams, Pittsburgh, U.S.A. Eng. Pat. 1443, January 28, 1890. 1s. 1d.

THIS invention is one in which metallic ores are reduced by means of carbonic oxide or other gaseous fuel. Its chief feature consists in causing the heated gas to travel

through the ore in a horizontal direction, by which means much less force is required to drive the gas and the ore is more thoroughly permeated. The furnace in which this principle is carried out is represented in the accompanying

THE REDUCTION OF METALLIC ORES.

Figure. A is the furnace in which D is a vertical space down which the ore passes, c, c^1 a checkwork of firebrick separated by horizontal shelves or diaphragms H H₁. The carbonic oxide first enters a previously heated regenerator K, then passes up the conduit M N into the checkwork c_2 . It then passes horizontally through the ore in D into the checkwork c^1 , as it experiences less resistance in taking this path than in passing vertically upwards through the ore in D. In c^1 it moves vertically upwards until it meets the obstruction H¹, when it again crosses over into C. In this way the heated carbonic oxide travels backwards and forwards until it reaches the exit R, whence it is led into a second regenerator where it is burnt. The reduced ore collects in a chamber F and is removed periodically through the exit G. When iron ore is being reduced the clute G communicates with an open-hearth furnace.—H. K. T.

Improvements in Apparatus for the Reduction of Argentiferous or other Zinc Ores. O. Lumaghi, St. Louis, U.S.A. Eng. Pat. 5407, April 9, 1890. 8d.

THIS is a modification of the Belgian zinc furnace. The retorts are charged at the lower ends, which are then closed with circular discs, having small tapping-holes which, however, are luted with clay in the early stages of the operation. The zinc vapours escape from the upper ends of the retorts through holes about 2 inches in diameter, which have been bored in the centre of what is generally the closed end of the retort. A condenser of the usual type is fixed to this end of each retort, but in a position slanting in the opposite direction. Thus it is maintained that both the retort and condenser sloping downwards from their point of contact the distilled zinc in the condenser cannot flow back into the retort, and any lead or other metal that may have become liquefied during the process will not contaminate the zinc, but will find its way to the other end of the retort, whence it may be readily tapped. Afterwards an air current is passed through the retort to obtain the "remaining zinc" to be recovered in the form of

oxide," and to roast anything left in the retort that may require it. The precious metals are recovered partly from the liquefied metal tapped from the retorts, and partly from the oxide of zinc.—A. W.

Improvements in the Production of Refractory Linings for Converter Bottoms, and in Apparatus therefor. B. Versen, Dortmund, Germany. Eng. Pat. 8295, May 28, 1890. 8d.

THIS invention consists of machinery for mechanically stamping converter bottoms. The converter is placed on a rotating table, and a stamper, provided with suitable mechanical motions, is brought down upon it.—H. K. T.

Improvements in a Process of and Composition for Softening and Subduing Refractory Ores. J. L. Hopper, Sarcoxie, U.S.A. Eng. Pat. 15,859, October 7, 1890. 4d.

THE ore is heated to a red heat and then immersed in a bath made up of the following ingredients:—

Pure water.....	10 gallons.
Common salt.....	5 lb.
Saltpetre.....	1 lb.

It is thus disintegrated and rendered easily reducible to powder. "The strong acid effect produced by the saltpetre" readily disintegrates the most refractory ores with but one heating, which if salt and water only were used would require "several heatings and baths to properly subdue them."—A. W.

Improvements in Tempering-Fluid for treating Steel. E. Tweedy, Danbury, U.S.A. Eng. Pat. 15,833, October 7, 1890. 4d.

THE fluid consists of water or oil mixed with oxide or carbonate, or both oxide and carbonate of iron, and an organic ingredient such as glucose. The mixture may be prepared in any way, but preferably the oxide and glucose are mixed together first in the proportion of one part of the former to two parts of the latter, and one ounce of this mixture is added to two gallons of water. When steel is heated to a dull red heat and quenched in this liquid, it is stated to be hardened to a greater depth than usual, and to be improved in other respects. Oxides or carbonates of manganese, cobalt, or nickel, may be substituted for those of iron, but they are less effective.—A. W.

Improvements in Compound Gold Wire. L. E. Burdon, Providence, U.S.A. Eng. Pat. 18,604, November 18, 1890. 8d.

THIS invention consists in the production of a compound bar having gold of a low grade in the centre, but of high grade at the surface. Such a bar when drawn furnishes wire suitable for the manufacture of pins, rings, &c. The compound bar may be produced by forming an external seamless tube of high-grade gold, within which is placed a core of lower grade and more fusible alloy, the two being made to unite by heating until the central portion fuses. Or a compound "disc" may be made, and this, by suitable machinery, converted into a tubular form, which, when drawn, gives a hollow wire.—H. K. T.

Improvements in the Reduction of Ores. H. W. Lash and J. Johnson, Pittsburgh, U.S.A. Eng. Pat. 19,163, November 25, 1890. 4d.

THIS is a process in which carburised iron is produced in a eupola furnace, instead of in the usual blast furnace. The ore is reduced to a fine powder, and mixed with powdered charcoal or coke, and the two incorporated together with water or oil until a thick coherent paste is produced. This is charged into a previously-heated eupola furnace, together

with coke, the latter being added in sufficient quantity to maintain the temperature and to prevent clogging. If desired, a flux such as lime-stone may be incorporated with the mixture or added along with the fuel. As the molten metal sinks down it is run off into an open-hearth furnace, and used as a highly carburised metal for the production of steel.—H. K. T.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

PATENTS.

Improvements in the Process for Obtaining Zinc by Electrolysis. A. S. Elmore, Rothwell. Eng. Pat. 17,205, October 30, 1889. 4d.

Porous cells are placed in a bath of zinc sulphate, or the bath is divided by porous partitions, an overflow pipe being attached to the porous cell or corresponding compartment to keep the level of the liquid in it slightly below the level of the liquid in the bath, and thus increase the flow through the pores. An anode of iron is placed in the porous cell and a disc or cylinder of suitable material serves as the cathode in the other compartment. The cathode is made to revolve, and as the zinc is deposited upon it, it is acted on by a burnisher pressed down by a weight or spring. This burnishing makes the deposited metal compact and close in texture.—B. T.

Improvements in Electric Battery Carbon and Carbon Compound Elements and their Connections. J. V. Sherrin, Ramsgate. Eng. Pat. 17,831, November 8, 1889. 6d.

To prevent corrosion of the terminals of a battery, the carbon is wrapped round with a piece of platinum foil, and a brass clamp fixed on with a set screw. The conducting wire is soldered or fixed in any convenient way to the brass clamp. Details are given of several kinds of connectors.—B. T.

Improved Means for the Prevention of Polarisation in Electric Batteries. H. Badcock, W. Grunsell, and A. Walker, Lynton. Eng. Pat. 19,199, November 29, 1889. 6d.

Two tanks are provided for the exciting fluid, one placed above the other, and the battery mid-way between the two; a pipe leads from the bottom of the upper tank to the bottom of the battery, and an overflow pipe from the top of the battery to the top of the other tank. If then a tap in the first-mentioned pipe be opened the exciting fluid will pass from the top tank through the battery into the lower tank, whence it can again be pumped up into the top tank to recirculate.—B. T.

An Improvement in or Connected with Incandescent Electric Lamps. H. Gardner, London. From W. Reid, New York, U.S.A. Eng. Pat. 58, January 2, 1890. 6d.

A REFLECTOR—preferably of diamond or lozenge section—is placed between the limbs of the filament, "to diffuse and improve the light, and to soften the glare."—E. T.

Improvements in and Connected with Primary Batteries. M. Sappéy, Paris, France. Eng. Pat. 488, January 10, 1890. 8d.

AN elaborate clockwork contrivance electrically governed for automatically emptying the spent liquids from and supplying fresh liquids to a two-fluid primary battery.

—B. T.

Process of Generating Electricity by Gas Batteries. O. Dahl, Allegheny, U.S.A. Eng. Pat. 761, January 15, 1890. Internat. Conv. June 17, 1889. 8d.

A SUITABLE furnace is brought to a sufficient temperature by means of an air blast, the gaseous products obtained (producer-gas) being stored for future use. Steam is then passed through the incandescent fuel and is decomposed with the production of hydrogen and carbon dioxide, the temperature not being allowed to rise high enough for the production of carbon monoxide. The gases so obtained are led through purifiers, which remove all but the hydrogen, to a gas-holder. When the furnace has become too cool to effect the decomposition of the steam, air is once more turned on, and the process repeated.

Sodium manganate is heated till it loses a portion of its oxygen, which may be replaced by heating the reduced compound in presence of air. The oxygen obtained is stored in another gas-holder.

The two gases thus produced are employed in any suitable gas battery for the production of electric currents.

—E. T.

Improvements in Means for the Electrolytic Generation of Chlorine and Compounds of Chlorine with Earthy Bases, more especially intended for Bleaching Purposes. D. G. FitzGerald and A. C. Falconer, London. Eng. Pat. 1216, January 23, 1890. 4d.

THE inventors make use of anodes of "lithanode" in the place of platinum or carbon as hitherto used, and place these anodes preferably in contact with the earthy chlorides to be decomposed. These anodes are not attacked by chlorine and do not become disintegrated by use.—B. T.

Improvements in the Coating of Iron, Steel, Nickel, Zinc, or Tin for the prevention of Corrosion. A. E. Haswell and A. G. Haswell, Vienna, Austria. Eng. Pat. 1355, January 25, 1890. 4d.

THIS invention consists in coating metallic articles by electrolysis with a thin layer of a metallic oxide, such as dioxide of manganese, sesquioxide of molybdenum, or dioxide of lead.

For the production of the manganese deposit the article is connected with the positive pole of a battery and immersed in a bath containing 50 to 100 grms. of manganese nitrate or sulphate and 2 kilos. of ammonium nitrate in 100 litres of water. For the production of the molybdenum deposit the article is connected with the negative pole, and is immersed in a bath of 100 grms. of ammonium molybdate and 2 kilos. of ammonium nitrate in 100 litres of water.

For the dioxide of lead deposit a bath of $\frac{1}{2}$ —1 kilo. of lead nitrate and 1—2 kilos. of ammonium nitrate per 100 litres of water is used, the article being made the positive electrode. The electric current required for the above depositions is weak, amounting to 0.3 to 0.5 ampère per square decimetre.—H. K. T.

Improvements in or Relating to Electric Accumulators. A. J. Boulé, London. From G. G. di Giovanni, Turin, Italy. Eng. Pat. 1629, January 30, 1890. 8d.

SHEETS of lead are passed between rollers which produce indentations or cells on each face of the sheet, the walls of such cells being left quite thin. The rolling produces small ribs or roughnesses on the bottoms of the cells. When the active material has been applied in any way to the plate, the whole is pressed, the cell walls being thus flattened and expanded so as to hold the active material safely. The lugs of the similar plates are fastened together by a long bolt, the contact faces of adjacent lugs being amalgamated to give better connexion. Combs and other devices for separating the plates are also described.—E. T.

Improvements in or Relating to Electric Accumulators. W. P. Thompson, London. From J. Peral, Cadiz, Spain. Eng. Pat. 8800, June 7, 1890. 8d.

THE plates are made up of a stout leaden frame with ribs of a section—

the ribs being also connected across by smaller ribs of diamond section to increase the stiffness and conductivity of the plate. The plates are then subjected to a side pressure so that the notched edges of the transverse ribs turn outwards and hold the active material firmly in position, thus—

Two ventilation tubes are provided to each cell, and are so connected that air can be forced through the cells to expel accumulated gases. An automatic cut-out is provided to cut each cell out as it becomes fully charged.—B. T.

Improvements in the Method of and Apparatus for Depositing Metals by Electro-Deposition. G. H. Felt, New York, U.S.A. Eng. Pat. 8933, June 10, 1890. 8d.

THE inventor states that if clay be treated with dilute sulphuric acid and a little nitrate of mercury added, aluminium alloyed with mercury may be electrically deposited. The clay is either added direct to the cathode compartment of a cell containing the sulphuric acid and mercury salt, or the solution is prepared beforehand. In the apparatus illustrated and described in the specification the anode is of amalgamated zinc.

The method is to be applied also to other metals.—E. T.

Improvements in Secondary Batteries and in Electrodes therefor. H. H. Lake, London. From G. A. Johnson and S. L. Holdredge, Boston, U.S.A. Eng. Pat. 12,830, August 15, 1890. 8d.

RECTANGULAR strips of the active material are enclosed in wide shallow boxes of lead, the sides of the boxes being perforated to allow of access for the electrolyte. Several types of boxes are described, one being formed of plates of lead with parallel and equi-distant ribs of the same metal, two sheets of lead being used to form each plate and burnt together with the ribs inside, and coinciding with each other so as to form a series of shallow boxes into which the active material is forced.—B. T.

Improvements in the Manufacture of Electrodes for Primary and Secondary Batteries. D. Pepper, jun., Philadelphia, U.S.A. Eng. Pat. 13,003, August 19, 1890. 6d.

THE active material is moulded round cores of fusible metal of suitable size and shape which extend some distance into the plate. The fusible metal is then removed and the metal which is to act as the support and metallic connexion of the finished plate is poured into the apertures, lugs of any desired shape being provided for.—B. T.

Improvements in the Manufacture of Electrodes for Primary and Secondary Batteries. D. Pepper, jun., Philadelphia, U.S.A. Eng. Pat. 13,013, August 19, 1890. 4d.

ABOUT 12 per cent. of a soluble and fusible salt, such as salts of ammonia, soda, potash, or magnesia, is added preferably to litharge, the two are thoroughly mixed, placed in a mould, and heated until the fusible salt is fused and a solid plate formed which may be used as an electrode in an electrolyte of sulphuric acid. For the positive plate oxidising salts, such as sodium nitrate, potassium chlorate, &c., are added to form the litharge into peroxide of lead.

—B. T.

Improvements in the Electrolysis of Melted Haloid Salts. G. O. Rennerfelt, Stockholm, Sweden. Eng. Pat. 13,024, August 19, 1890. 4d.

To remove the melted metal from the cathode compartment a pipe is led from this compartment to a vessel serving as the receptacle for the melted metal, and thence is carried on to an exhausting apparatus by means of which the pressure at the cathode is made lower than the ordinary atmospheric pressure, so that the molten metal is carried over from the cathode.—B. T.

An Improved Battery Compound. C. M. Reed, Boston, U.S.A. Eng. Pat. 13,807, September 2, 1890. 4d.

THE new fluid is formed from chromium trioxide and ammonium chloride dissolved in water containing a little sulphuric acid in proportions varying according to the purpose for which the battery is to be used. This compound may be used in either a single- or a double-fluid battery.

—B. T.

An Improved Method of Obtaining Metallic Sodium. L. Grabau, Hanover, Germany. Eng. Pat. 16,060, October 9, 1890. 4d.

IN the usual method of obtaining sodium by the electrolysis of fused sodium chloride great loss of metal occurs owing to the formation, at the red heat necessary for the operation, of subchloride of sodium as shown by H. Rose and Bunsen, the subchloride being partially oxidised at the surface of the bath, partly diffusing to the positive electrode where it combines with the liberated chlorine. To obviate these difficulties the author uses a mixture of 1 mol. of potassium chloride to 1 mol. of sodium chloride; 1 mol. of the chloride of either barium, strontium or calcium being added for every 3 mols. of the mixed alkaline chlorides. Such a mixture fuses at a temperature considerably below a red heat, and the subchloride is not formed if the mixture be kept at its fusing point. The resulting sodium contains about 3 per cent. of potassium but is free from alkaline earthy metals. Strontium chloride is preferred to calcium chloride owing to the difficulty of completely expelling moisture when the latter salt is used.—H. K. T.

Improvements in Insulating Cells for Electric Batteries. S. C. C. Carries, Philadelphia, U.S.A. Eng. Pat. 16,322, October 14, 1890. 8d.

To prevent leakage the cells are provided with a depending rim all round, this rim not being in contact with the floor or support for the cells, but the base of the cells resting upon a pillar of suitable material with a cup-shaped recess or moat formed in and running all round its sides, in which recess an insulating fluid can be placed. The depending rim does not touch this supporting pillar, so that all leakage from this cell to earth must take place across the insulating fluid.—B. T.

Improvements in the Method of and Apparatus for Casting Frames or Supports for Battery Plates or Elements. H. H. Lloyd, Camden, U.S.A. Eng. Pat. 16,324, October 14, 1890. 8d.

To prevent any dross or scum being ladled into the mould with the melted metal, the latter is forced by compressed gas right from the bottom of the crucible, where such contamination is impossible, the stream of melted metal being led through pipes to the mould, without being exposed to the air at all. The compressed gas may be air, but is preferably water or other gas which will have, if any, a reducing action.—E. T.

Improvements in Secondary Batteries. C. W. Kennedy and H. Grosz, Philadelphia, U.S.A. Eng. Pat. 16,571, October 18, 1890. 8d.

LEAD plates are cast with small knobs arranged in parallel rows upon one side and with a thickened flange or edge on the other side, so that when two of these plates are bolted together with the knobs outside, the flanges coincide and leave an empty space between the plates. The finished plate consists of two of these plates bolted together as above, the space between being filled with active material and holes being bored through the lead from the outside so as to leave a burr on the inside, which serves to retain the active material in position. Any suitable number of these plates are used in each cell, the complete plates being bolted together by insulated bolts and spaced apart by ebonite distance pieces. A plate is also described, made up of a body of very thin steel or other metal, coated with an unbroken film of lead.—B. T.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

Indian Grass Oils. F. D. Dodge. Amer. Chem. J. 12 533—564.

See under XX., page 158.

PATENTS.

A New and Improved Manufacture of Soap. C. Billing, Scaforth. Eng. Pat. 13,700, August 30, 1889. 6d.

By incorporating an ordinary soap with a mixture of mineral hydrocarbon oils (preferably boiling at about 200° F.) and turpentine, considerable advantages are said to be obtained. The paraffin retards the volatilisation of the turpentine, and the latter acts as a solvent to the former. A large amount of paraffin may be used in a soap without separation of the paraffin taking place when treated with water. No other method, so far as the inventor is aware, allows a greater addition than 3 per cent of paraffin oil to soap without making the soap soft and friable, and giving rise to separation of paraffin on dissolving with water.

—K. E. M.

Improvements in the Manufacture of Sheep Dip. G. Craig, Dalry. Eng. Pat. 889, January 17, 1890. 4d.

See under XVIII. C., page 156.

Improvements in Soap and Soap-Powder for Use with Hard and Sea Waters. H. Grimshaw, Manchester. Eng. Pat. 983, January 20, 1890. 4d.

ALKALINE phosphates are incorporated with soap or soap-powder.—K. E. M.

Treatment of Press and Extraction Residues of Oil Manufacture for Obtaining Valuable Products therefrom. H. Noerdlinger, Stuttgart, Germany. Eng. Pat. 1109, January 21, 1890. 6d.

See under XVIII. A., page 155.

Improvements in the Treatment or Utilisation of Salt Obtained from Spent Soap Lyes in the Recovery of Glycerin therefrom. C. W. Hazlehurst and S. Pope, Runcorn. Eng. Pat. 1126, January 22, 1890. 4d.

THE organic impurities in the salt obtained by the glycerin recovery process from spent lyes are destroyed by heat in presence of air.—K. E. M.

Improvements in the Process of Cleaning and Extracting Oil and Grease from Cotton-Waste and other Fibrous Materials. D. Barnett, St. Peter's Park. Eng. Pat. 1652, January 30, 1890. 8d.

See under V., page 134.

Improved Process and Apparatus for the Manufacture of Kneaded or Agglomerated Soaps. A. des Cressonnières and E. des Cressonnières, Brussels, Belgium. Eng. Pat. 2446, February 14, 1890. 8d.

WITH a view to save labour, time, and interest on capital in the manufacture of kneaded soaps, the inventor substitutes for the soap frames, cutting machines and all processes necessary for the manufacture of dry soap shreds, used for milled soap from a soap-paste, a continuous apparatus which cools, dries and cuts up into shavings the liquid soap. The latter flows over a series of hollow cylinders contained in a chamber, where it meets with currents of air which cool the soap and deprive it of moisture during its passage between the cylinders, these rotating in contrary directions and each successive cylinder increasing in speed. On leaving the last cylinder the soap is cut into ribbons and finally dried on endless travelling wire-webs which convey it to the pressing apparatus.—K. E. M.

An Improved Process for Producing Ozonised Oils. F. Pickenbrock, Berlin, Germany. Eng. Pat. 4137, March 17, 1890. 4d.

See under XX., page 159.

New or Improved Machinery or Apparatus for Crushing and Blocking or Moulding Toilet Soap. A. and A. Beyer, Paris, France. Eng. Pat. 4939, March 29, 1890. 8d.

THE improvements consist in the combination of a crushing and moulding apparatus for toilet soap to form a single machine: a new method of mounting the crushing cylinders and of regulating the distance between them and a new arrangement of scrapers, which can be placed on different sides of the uppermost crushing cylinder dividing the soap into ribbons. For details of these improvements the original drawings must be referred to.—K. E. M.

An Improved Method of and Apparatus for Extracting and Purifying Perfumes, Oils, and other like Substances. H. H. Lake, London. From "La Société Anonyme des Parfumes Naturels de Cannes," Paris, France. Eng. Pat. 5940, April 18, 1890. 1s. 3d.

See under XX., page 159.

Improvements in the Manufacture of Cod-Liver Oil. C. A. Jensen, London. From P. Möller, Christiania, Norway. Eng. Pat. 13,803, September 2, 1890. 4d.

ACCORDING to the inventor the unpleasant taste of cod-liver oil is due to products of oxidation, mainly oxy-acids, which cannot be avoided by the process of manufacture at present in vogue. To prevent the objectionable effect of oxidation the fresh cod-liver is treated in a closed instead of an open vessel and an inert gas or fluid is forced through it to expel contained air.—K. E. M.

Improvements in and Relating to Lubricants and Joint-Making Material. A. Purvis, South Shields. Eng. Pat. 13,936, September 4, 1890. 4d.

Two cwt. of Japanese tallow, 3 cwt. of Russian tallow, 108 lb. of lard oil, 108 lb. of castor oil, 2 cwt. of specially prepared olive soft soap, 10 lb. of carbonate of lime, 10 lb. of carbonate of soda are submitted to a very high temperature (preferably 210° F.), thoroughly mixed with $\frac{1}{2}$ cwt. of finely pulverised mica or kaolin (china clay), or a mixture of these, cooled, re-heated after 24 hours' standing, and 20 lb. of oxide of zinc added; then all steam and water is forced out by hydraulic pressure. The lubricant is stated to minimise the effect of water on the bearings of machinery, and will not become fluid in hot climates or in the engine-room.—K. E. M.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

Studies upon Resins. L. H. Friedburg. J. Amer. Chem. Soc. 1890, 12, 285—291.

THE author commences a series of studies on resins with an investigation of copal.

Copals are either *soft*, like damar, and soluble in ether, *half-hard*, or *perfectly hard*, in which case they can only be entirely dissolved after some chemical change. Soft copals are found mainly in Sumatra, Java, Molucca, the Philippines, and Australia. Hard copals are imported from Zanzibar and the African coast via Calcutta, and from Madagascar, Mauritius, and Bourbon via Bombay. The last kind probably comes from a tree, *Hymenaea verrucosa*, known in the Mauritius as a *copallier*. The *Hymenaea courbaril* furnishes a similar product (H. Violette, *Fabrication des Vernis*, 302—304). The growers mix together hard and soft copals pell-mell, and ship them as hard copal and the dealers assort them; so that judgment must be exercised in order to secure a uniform quality. Hard copal is insoluble as a whole in alcohol, ether, and turpentine, but becomes soluble in the last two liquids on heating. In making varnishes, copal is melted and heated up; turpentine is boiled at the same time, and slowly run into the copal. If the copal is not hot enough, or the turpentine run in too fast, a clear solution is not obtained. Many patents for modifications of the process have been taken out (see Ure's Dictionary, 7th Ed., 1055), but the chemical reactions are not understood. The author has studied the decomposition of copal by heating in a flask with a Liebig's condenser. A light flowing distillate, probably containing Wallach's *limonen* (Annalen, 252, 108), is obtained from 100° C. to 185° C.; then white vapours, only partially condensable, come off, till 215° is reached, when the mass becomes very dark, boils quietly without any visible vapour, and the thermometer falls suddenly and rapidly to 170° C.

It seems to follow that up to 215° fractional distillation takes place, but above that temperature real decomposition sets in. When copal is heated to 182°, one-third part by weight distils off, and on cooling a brilliant, hard, glassy translucent mass is obtained, easily soluble in cold or warm turpentine.

Distillation by means of steam under 45 lb. pressure yielded the terpene compound and a residue insoluble in turpentine. Copal may be dissolved in the liquid produced by its own destructive distillation, but this is an evil-smelling product. It may also be dissolved in aniline and its homologues, nitrobenzene, chloroform, phenol (patented process), and cineol (for this substance, see Annalen, 225, 295).

Benzaldehyde has a peculiar action on copal. The copal first dissolves perfectly, but soon thickens to a light amber-coloured jelly. When the ground copal is treated in a flask with benzaldehyde, after clear solution, the jelly state is reached at 80° C. Then thick yellowish masses, benzaldehyde, water, &c. distil off, and finally an oil which condenses in thick white crystals, soluble in ether and benzaldehyde.

The products showed an increase of 8 per cent. over the original substance. The distillate probably absorbs atmospheric oxygen. This reaction will be further studied.

Turpentine inverted at 270° C., "seemed to be a solvent." Glacial acetic acid dissolves copal partially. Copal takes up carbon disulphide in large quantities as a colloid, and is also partially soluble in it, yielding (1) a plastic mass, which becomes hard on exposure to air; and (2) a solution which evaporated on the water-bath, yielded a gummy light-yellow coloured mass of aromatic odour. Glycerin is not etherified by copal when heated with it under atmospheric pressure. Increased pressure has not yet been tried. Concentrated sulphuric acid oxidises copal, sulphur dioxide being given off. Chromic acid, even at the boiling point, does not act on it. Potassium dichromate and sulphuric acid together act on copal energetically, yielding a product smelling like leaves of *Asperula odorata*. Caustic soda, 40° B. does not act appreciably on copal. Potassium permanganate attacks it at the boiling point. Nitrosylsulphuric acid acts on copal without violence, yielding a mahogany-coloured product, probably a nitro-compound, insoluble in water, soluble in alkalis. Sulphur introduced into boiling copal yields sulphuretted hydrogen, and the mass becomes hard and black.

Reducing substances give a very strong reaction with copal.

Alcoholic ammonia acts strongly on copal when warm. The solution produced deposits sulphur, and a white solid compound when neutralised by acids. The residue in alcohol, when boiled with water, puffs up to a porous mass, which, when dried, is found to be entirely volatile, and is probably an ammonium salt. Aqueous ammonium sulphide partly dissolves copal at the boiling point to a blood-red solution, which becomes lighter on cooling. Grape sugar in alkaline solution acts violently on copal. Potassium ethylate acts on copal on heating moderately. Strong hydrochloric acid attacks it slightly. Zinc dust heated with the substance gives condensable and non-condensable hydrocarbons. Iron dust, and zinc and hydrochloric acid do not act on it.

The author thinks crude copal consists of three typical compounds: (1) a terpene; (2) an easily-oxidisable compound not a terpene; and (3) an acid which may be homologous to abietic acid, and which forms the amorphous, vitreous, translucent mass.

The experiments are to be repeated quantitatively.

—P. J. H.

PATENTS.

Improvements in the Manufacture of White Pigments, principally composed of Sulphate of Lead. J. E. Wood, Shirehampton. Eng. Pat. 19,910, December 11, 1889. 4d.

THE raw material, consisting mainly of lead sulphate often mixed with lead oxide and zinc salts, is washed with a solution of sodium carbonate containing about 5 per cent. of the weight of the pigment operated on, of the dry salt. The result is to transform some lead oxide and sulphate and the zinc salts into carbonates of the metals. This is said to improve the material as a pigment, causing it to dry more readily, but removing the tendency to set hard, as lead sulphate paints are stated to do. The colour is also said to be improved.—B. B.

An Improved Method of making Paints and Varnishes, and the Treatment of Gums and Resins for the same, for Preservative, Decorative, and Artistic Purposes; also for preventing the Plates of Iron and Steel Ships from Corrosion and the Bottoms of Ships from Fouling. R. Mullard, London. Eng. Pat. 20,707, December 24, 1889. 6d.

Any suitable gum or resin capable of combining with bases to form the bodies generically termed resinates is boiled with ammonium, potassium or sodium hydrate and the resulting solution precipitated hot with a suitable metallic salt, such as those of copper and lead. The resulting resinate is then dissolved in any suitable solvent, such as turpentine or naphtha, and may be used direct as a varnish, or it may be dissolved in linseed oil and mixed with the ordinary ingredients of an oil varnish. Paints may be prepared by adding to the resinate linseed oil, turpentine and a pigment, which is preferably one containing the same metal as that forming the base of the resinate.

Anti-corrosive mixtures may be made from resinates of which iron is the base mixed with "oxide of iron," asphaltum, coal-tar, or pitch; "benzole" may replace turpentine as a solvent. Anti-fouling compositions may be formed by adding carbolic or cresylic acid or beechwood creosote.—B. B.

An Improved Process and Composition for producing Printing Ink. C. Huelser, London. From G. Cullman, Weimar, Germany. Eng. Pat. 20,830, December 28, 1889. 4d.

See under VI., page 135.

Improvements in Compositions to be used as Paints. W. H. Barnes, London. Eng. Pat. 764, January 15, 1890. 4d.

"BRIGHT VARNISH," such as is used for mast yards and other woodwork (otherwise known as "pine varnish") is taken as a basis for various paints in place of ordinary drying oils, such as linseed oil; the presence of these latter materials must be avoided save with certain exceptional samples of bright varnish. Paints made therewith dry with a glossy surface unless specially treated as described below. The patentee finds that the cheapest and darkest samples of bright varnish are generally best for his compositions, but he uses the following test to make sure of their suitability: $1\frac{1}{2}$ fluid oz. are mixed with 1 fluid oz. of turpentine, and enough zinc white to form a mixture of the consistency of an ordinary paint; this is brushed on a clean piece of iron, and will dry in half an hour to an hour if the varnish be of proper quality. White and red lead added to bright varnish for the production of paints cause it to dry considerably and even become semi-solid; this inconvenience can be remedied by the use of zinc white added dry or ground in turpentine. Various mixtures are quoted in the specification, usually consisting of bright varnish, zinc white, turpentine (or some turpentine substitute), a pigment of the colour of the finished paint, and resin. Zinc driers are generally used in preference to the common lead driers. When zinc white is inadmissible, the bright varnish may be boiled to drive off part of its volatile constituents, and thinned with turpentine or alcohol.

For flatted paints the varnish is mixed with pigments containing lead and allowed to thicken for about 48 hours; the solidifying process is then checked by the addition of zinc white; whiting or china clay may be added to perfect the power of the paint to dry with a dull surface. Such materials as Stockholm, Bordeaux, or Venice turpentine may also be used in the preparation of such paints.—P. B.

A New or Improved Liquid applicable as an Adhesive Insecticide Paint or Varnish, or the like. J. Jeyes, Stratford. Eng. Pat. 853, January 16, 1890. 4d.

FORTY parts by weight of common rosin, 17 of caustic soda solution of 30° B., and 180 of water are boiled together "until perfectly combined." The mixture may be used for papering walls or sticking posters. By adding to this mixture 24 parts of dextrin the fluid can be used for adhesive labels. By diluting the original mixture with 4—6 parts of water it can be used for dipping iron goods in to prevent rust, and by adding 1 part of methylated spirit, "turpentine spirit, or benzine spirit, or petroleum spirit," to 3 parts of the original mixture, a varnish is obtained for inside work of houses and for toys. The composition is claimed as an insecticide in the provisional, but this claim is omitted in the complete specification.—B. B.

Mould for Vulcanising India-rubber Tyres and Rings. A. J. Ruth, Hyde. Eng. Pat. 1268, January 24, 1890. 6d.

RINGS provided with top and bottom grooves are laid one upon the other to form a series of annular matrices for moulding such articles as india-rubber tyres. Before building up these rings into a series they are filled with a plastic mixture of the rubber to be vulcanised in the ordinary way, then placed in position, clamped so as to form steam-tight joints, and the tyres vulcanised by admitting steam to channels provided in the rings for that purpose. Tyres of several sizes may be turned out simultaneously by using rings having several concentric grooves instead of one only.—B. B.

Improvements in or Pertaining to Drums or Vessels with Covers for Containing Substances, such as Anti-fouling Compositions and Paints, having Constituents Liable to Settle. V. B. Lewes, Greenwich. Eng. Pat. 1757, February 1, 1890. 6d.

THE vessel containing the anti-fouling composition is provided with a vertical central rod attached to its cover, the rod carrying arms or a screw blade at its lower part. The cover is screwed on to the vessel, and in the act of unscrewing it to empty the vessel the vertical rod with its attachments is revolved, thus stirring up the contents. In one form illustrated, the cover is not screwed on to the vessel, but, instead, the vertical rod at its lower end screws on to a pin projecting from the bottom of the vessel, the object of either arrangement being simply to ensure the revolution of the vertical rod and its blades on opening the vessel.—B. B.

Medium for Use with Chemical and Earth Colours. E. Schumahl, Berlin, Germany. Eng. Pat. 13,719, September 1, 1890. 4d.

"THIS invention relates to a process for the production of a binding composition or medium for adding to earth and chemical colours instead of the oil and glue or size ordinarily used for the purpose." The mixture consists of the following ingredients, variation in the proportions being permissible:—10 parts of linseed oil, 10 of borax, 5 of dextrin, 2 of glue or size, and 6 of rye or maize flour. The advantages claimed are greater durability and less smell than those of ordinary paints, and freedom from tendency of the colours to run into one another when applied to woven fabrics.—B. B.

Improvements in the Manufacture of Linoleum, Lincrusta, Cere-Cloth, and the like. G. Schüler, Stettin, Germany. Eng. Pat. 15,170, September 25, 1890. 4d.

DYING linoleum depends upon the oxidation of the linseed varnish, serving as agglutinant. The inventor effects this oxidation by mixing the material with chemicals which deliver oxygen at moderate heat, such as chloride of lime or chromic acid. The mass is then laid on the tissue, and the

linoleum or other substances heated by being passed over hot rollers or plates. The quantity of chloride of lime, for example, used is 8 to 10 per cent. of the varnish. It is stated that this process has a very favourable influence on the quality of the products.—H. S.

Improvements in Floor-Cloth, Applicable also to American Leather-Cloth and to Leather used for Upholstering or other Purposes. A. Frampton, London. Eng. Pat. 16,058, October 9, 1890. 4d.

A LAYER of felt, feltine wool, hair, cotton, paper, or india-rubber cork, is attached to the underside, or inserted between two layers of floor-cloth or American leather-cloth, &c., by means of glue. This considerably increases the durability of the cloth, and renders it soft and elastic.—H. S.

An Improved Ink for Printing and Similar Purposes. H. H. Lake, London. From W. G. Fnerth, Newark, New Jersey, U.S.A. Eng. Pat. 16,689, October 20, 1890. 4d.

See under VI., page 136.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

PATENTS.

Improvements in and Connected with the Recovery of Tannin from Waste Leather. H. Grimshaw, Manchester. Eng. Pat. 981, January 20, 1890. 4d.

THE waste leather is steeped in an alkaline solution of an alkali or alkaline earth the tannate of which is soluble. A solution of hydrate or carbonate of soda is preferable, and may suitably contain about 10 per cent. of soda. The treatment is continued until the tannin is removed from the leather and is in solution in the form of tannate. The tannin may be removed from the solution by any known means, and the untanned leather waste may be employed for various purposes, such as those for which hide clippings, &c. are generally used.—B. H.

Improvements in Preparing and Waterproofing Skins for Various Purposes. W. Dyshko, St. Petersburg, Russia. Eng. Pat. 16,017, October 9, 1890. 4d.

THIS invention is for a waterproofing composition composed of the following ingredients:—Colophony, 1 part; blubber, 1 part; wax, 2 parts; oil of turpentine, 1 part. In the manufacture of waterproof boots not only is the upper leather treated with the composition but the soles, insoles, and side linings, and also a piece of kid which is placed inside the boot between the upper and the side linings.

—B. H.

XV.—MANURES, Etc.

Report on the Progress in the Manufacture of Artificial Manures. Chem. Ind. 1890, 13, 386—387.

THE manufacture of artificial manures is becoming more and more troublesome, inasmuch as the better kinds of raw material are getting constantly scarcer and necessitates the employment of ferruginous and aluminous materials, in which the problem of making the phosphoric acid soluble

and non-revertable has not yet been solved. German manufacturers have striven and succeeded in producing a better material than the manufacturers of other nations, but then the question of cost has led even their fellow countrymen to avail themselves of the cheaper and inferior foreign products.

The mixing machine of Lorenz of Hanover has an arrangement of knives in a narrow deep vessel, which ensures a more thorough stirring up and mixes the materials more quickly and more intimately with the acid, than the old mixing machine. The same inventor has introduced what promises to be a successful mixer for dry materials.

—D. A. L.

Bone Meal. J. König. Landw. Versuchsst. 1890, 38, 81. The author proposes to fixly define the various sorts of bone meal in the following manner:—

(a.) "Normal bone meal" or "Bone meal, No. 0" he terms that which is obtained from whole bones previous to preparation for extraction and containing 4—5·3 per cent. of nitrogen and 19—22 per cent. of phosphoric acid. After extraction with chloroform, the relation of nitrogen to phosphoric acid should be 1 to 4, and up to 5·5.

(b.) Bone meal containing 3 to 4 per cent. of nitrogen, and 21 to 25 per cent. of phosphoric acid, and in which, after extraction with chloroform, the relation between nitrogen and phosphoric acid is 1 to 5·5 up to 8·5, to be designated merely "bone meal."

(c.) Bone meal containing 1 to 3 per cent. of nitrogen and 24 to 30 per cent. of phosphoric acid, and in which the relation of nitrogen to phosphoric acid after treatment with chloroform is 1 to 8·5 up to 30 to be considered as "deglutened bone meal."

(d.) To the class of "crude bone meal" belongs the material obtained by merely crushing the bones, and the purity of which may be judged by its outwards appearance.

(e.) Meals containing, after treatment with chloroform, less than 1 per cent. of nitrogen, and in which the relation of nitrogen to phosphoric acid is higher than 1 to 30, cannot be considered as bone meals, but may be termed "mixed manure meals."

The manure obtained from flesh may be called "flesh meal" or "flesh manure meal."—T. L. B.

Application of Thomas Slag to Fruit Trees. Tschaplowitz Gartenflora, 1890, 39, 348—353.

VARYING quantities of mixtures containing 4 parts of Chili saltpetre, 3 parts of potassium sulphate, and either 60 parts of 18 per cent. "Thomas" slag, or 30 parts of 18 per cent. superphosphate were applied to fruit trees on a shallow sandy soil with clayey sub-soil. In some few cases one or the other phosphate showed superiority, but on an average the double quantity of slag proved as effective as the single allowance of superphosphate, both being beneficial.

—D. A. L.

XVI.—SUGAR, STARCH, GUM, Etc.

Leopard-Tree Gum. J. H. Maiden. Trans. Australasian Assoc. Advance. Science, 1890, 379—380.

Flindersia maculosa, found in New South Wales and Queensland, belongs to the natural order *Meliaceae*, and owes its name of "spotted or leopard tree" to the peculiar markings on its bark; it is also known as "dogwood" and as *F. strzeleckiana*. Large quantities of clear, amber-coloured, pleasant tasting gum exude from the stem and branches during the summer, sometimes exuding very rapidly, at other times remaining in a liquid state on the tree for some little time. It is eaten by the natives, is commonly used by bushmen as a remedy for diarrhoea,

and it makes a good adhesive mureluge. Of two samples in the Technological Museum, Sydney, one is a most valuable gum, clear, of excellent quality, completely and readily soluble in cold water, yielding a practically colourless solution with a faint cloudiness like that assumed by aqueous solutions of gum arabic. The other sample, apparently contaminated with dust while exuding, and consequently of reduced value, is dull and dirty looking, almost colourless, very brittle with a bright fracture, and is regarded as most frequently the product of half-dead trees.

The two samples have the following composition:—

	Arabin.	Water.	Ash.	Total.
Sample 1.....	80.20	16.49	2.76	99.45
Sample 2.....	80.68	16.40	2.63	99.11

metarabin being absent in both cases; leopard tree gum is therefore to all intents and purposes a good gum arabic. This is the only Australian species of *Flindersia* known to the author to yield gum.—D. A. L.

On the so-called "Sulphite Lye" and on the Rotation of Gluconic, Galactonic and Rhammonic Acids. F. Weld, J. B. Lindsay, W. Schuelle, and B. Tollens. Ber. **23**, 2990—2992.

See under XIX., page 156.

The Manufacture of Rice Starch. J. Berger. Chem. Zeit. **14**, 1410, 1557—1558, and 1571—1574.

Rice starch has replaced wheaten starch to a considerable extent in Germany, where the annual production is, at present, about 40,000,000 kilos.

The raw material employed is obtained from rice-cleaning and polishing mills, and consists of the broken grains. The composition of various samples of this waste is given below:—

	East Indian Rice.			Russian Rice.	Egyptian Rice.	Persian Rice.
	Per Cent.					
Water.....	12.10	13.20	13.23	12.70	11.84	10.80
Starch.....	76.25	73.90	77.44	75.81	78.30	73.20
Protein.....	8.95	8.79	6.87	7.94	6.70	11.21
Fat.....	0.42	0.71	0.35	0.40	..	0.75
Gum and sugar	0.86	1.20	0.95	1.21	..	1.45
Fibre.....	0.32	0.40	0.36	0.44	..	0.81
Ash.....	1.10	1.86	0.80	1.45	1.16	1.78

The value of a sample for starch manufacture depends on the amount and quality of the starch it contains, and on the percentage of proteins, and the solubility of the latter in soda solution. The following scheme of analysis is suggested:—

1. The total percentage of starch is estimated by Lintner's process. 1.2 is subtracted from the result, in order to correct for the gum and sugar which are included in it.

2. The total nitrogen is estimated, then—

$$N \times 6.25 = \text{proteins.}$$

3. The soluble proteins are determined by digesting a known weight of rice with soda solution at 1 B. From the solution the proteins are precipitated by neutralisation with an acid and weighed.

4. The residue of rice from 3 is ground up with weak lye, filtered through silk, and centrifugated. A paste is made of 6 grms. of the purified starch and 100 cc. of water. The paste is tested for consistency, &c.

The nitrogenous bodies present in rice are not nearly so easily separated from the starch as in the case of wheat. The application of soda solution is always necessary in order to dissolve more or less of the proteins, and render the starch soft enough for grinding. The operation is usually carried out in shallow tanks of 4—5 cbm. capacity. The rice is piled on a perforated shelf fixed in the tank, and covered with soda-lye at 0.5 to 1 B. The mixture is stirred a few times, and after about 18 hours the lye is run off and replaced by a fresh portion, which is allowed to remain for 12 hours, by which time the starch is generally sufficiently softened. The great importance of this softening process is not sufficiently recognised, and in consequence it is often negligently performed. Apart from this, however, the above method is faulty. Carried on, as it is, in open vessels, with only very occasional stirring, but little of the nitrogenous bodies are dissolved; further, owing to the length of standing, fermentation is liable to set in, especially in warm weather. The evil effects of fermentation are noticeable in all the after-processes. It causes the mass to froth excessively in the grinding mill and centrifugating is rendered very difficult. The starch does not separate in a state of purity, and comes from the centrifugals in flabby lumps. For the same reason it refuses to deposit in the settling tanks. The protein assumes a slimy condition and retains much starch. Even if the fermentation be stopped by means of sulphurous acid, it easily recommences during the drying of the starch, so that the latter becomes more or less mouldy.

The author therefore recommends that the extraction and softening of the rice be effected by a continuous current of lye. By this means the time of treatment is considerably shortened. The action is also rendered more energetic by using a stronger solution of soda, say, at 1½ B. In such case, however, it is necessary to cool the liquid, otherwise the starch might suffer. In the old process, 2 cbm. of soda-lye are required for 1,000 kilos. of rice, which corresponds to a quantity of sodium hydrate equal to 1—1½ per cent. of the weight of the rice.

After soaking the rice is ground. This operation is in most cases effected between mill-stones of about 1,200—1,400 mm. diameter, and 300—400 mm. in thickness, making 120—140 revolutions per minute. The process must be most carefully watched in order to avoid incomplete grinding. All lumps, &c. are rejected by the sieves in the course of the working, and pass into the waste. It is therefore customary in most manufactories to pass the rice through two mills, arranged side by side, so that the cream of starch drops directly from the first into the second mill. During grinding the rice is moistened with lye of the same strength as that used for softening, about 200 litres being required per 100 kilos. of original rice. The creamy mass flowing from the mill contains about 20—28 per cent of solid matter. 200 cwt. of rice may be ground in a double mill in 24 hours. The ground mass is lifted into high-lying tanks from whence it is distributed to the sieves and other apparatus. The pure starch is separated from the impurities by means of sieves, centrifugal machines, settling tanks, and filter-presses.

Sieves.—Rotating cylindrical sieves are almost exclusively employed. They are constructed as follows: A shaft 4—5 metres in length is provided at intervals of 1 metre with three rods of equal length, arranged symmetrically at right angles to the shaft. The ends of these rods carry six wooden boards parallel to the shaft. The framework thus formed is covered with the finest silk gauze. The cylinder is so arranged that one end lies about 15 cm. higher than the other. The liquid to be strained is fed into the upper part of the apparatus. The filtrate is collected in a wooden casing which completely surrounds the cylinder. The lower end of the cylinder projects beyond the outer box, into a tank into which the impurities remaining on the sieve are washed. The shaft of the cylinder is hollow, and is pierced by numerous holes through which water can be forced. By this means the walls of the cylinder are kept clean, and the

passage of the impurities to the lower end is facilitated. The waste obtained contains very little starch, and may be used as cattle food. The starch-milk passing through the sieve still contains much protein, which may be separated by centrifuging or by treatment in settling tanks. The former process requires less time and space but more power than the latter.

Centrifugal Machines.—The drum of the centrifugals usually employed consists of copper or iron, and has a diameter of 800–900 mm. and a depth of 340–400 mm., the removable head having a height of 150 mm. The drum is not perforated and makes about 1,400 revolutions per minute. When charged the apparatus is kept running for 15–25 minutes according to circumstances. The starch and gluten adhere to the walls of the drum in layers, the starch being innermost, and are separated by scraping, each being ground up with water and again centrifuged.

Settling Tanks act similarly to centrifugal machines, the starch settling to the bottom, whilst the gluten remains suspended in the water and is drawn off.

Filter-presses are only employed to remove soluble impurities.

When the various processes are employed in the order given, the yield of starch of the first quality is about 60 per cent. (calculated as absolutely dry starch on the rice), whilst 7–10 per cent. are left in the various by-products and may be recovered by repeated centrifuging, &c. The total yield is about 85–90 per cent. of the starch contained in the rice.

Moulding the Rice.—Formerly this was almost exclusively done in wooden boxes with perforated bottoms covered with filtering cloth. The boxes are set up in rows, and the starch mixed with water or weak soda-lye (0·1° to 0·3° B.) being charged into the first box, overflows into the next, and so on. In order to make the water drain out more thoroughly the boxes are repeatedly lifted from their supports and dropped again. After about 24 hours the blocks of starch, still containing 42–44 per cent. of water, are removed and cut into rectangular pieces. Various forms of high pressure filtering moulds are now employed, and with these the starch-milk used for filling must not exceed in specific gravity 1·2–1·25, otherwise the finished product exhibits a rough fracture, which detracts from its appearance.

Preliminary Drying of the Starch.—Blocks of starch containing 40–45 per cent. of water, when dried become covered with a yellow crust, owing to the separation of traces of dextrin, &c. This crust is about 10 mm. thick, and is cut off when the blocks are partially dried, *i.e.*, contain 25–28 per cent. of water. The remaining starch may be now completely dried without any further development of yellow colour taking place. All attempts hitherto made to avoid this crust formation have failed. The crust constitutes about 22–30 per cent. of the total starch. The shavings are stirred up with water, centrifuged once, or filtered, and mixed with the following batch of pure starch. Large masses of starch when dried fall into more or less irregular rod-like pieces, the size, shape, and smoothness of surface of which depend greatly on the rapidity of drying and the solidity of the blocks before drying. Starch is generally coloured in order to hide its slightly yellow tint, ultramarine being usually employed for the purpose. The blocks remain in the drying chamber for 14–21 days according to the temperature, which ranges from 30°–50° C. The dried starch contains about 12 per cent. of water, but on exposure to air it absorbs moisture up to 15 per cent., which is the commercially recognised standard. If it be desired to obtain the starch in large lumps, the blocks after scraping are cut up into smaller pieces, which are then slowly dried in the air.

Waste Products.—These consist of gluten and impure starch. They may be mixed and used for cattle feeding; or more or less separated and utilised, the starch for feeding and the gluten for manurial purposes.—H. T. P.

Gums from Two Species of Ceratopetalum. J. H. Maiden, Trans. Australasian Assoc. Advance. Science, 1890, 381–383.

The genus *Ceratopetalum* belongs to the natural order *Sarifrageae*, and is endemic in New South Wales.

C. gummiferum is generally of bushy size but occasionally develops to a small tree; it bears a reddish persistent showy calyx and constitutes the “Christmas bush” of Sydney and has been known as the “officer plant.”

C. apetalum, a gully tree only found in moist situations, is tall with smoothish bark, bright-looking foliage, and an abundance of white flowers, and is locally known as “coach-wood,” “lightwood” and “leatherjacket.”

C. gummiferum yields a transparent ruby-coloured gum with bright fracture, a powerfully astringent taste, and sticks to the teeth. To obtain this gum in considerable quantities ring-barking, or wounding the tree, or mere cutting down is of little avail; the tree must be cut into logs or pieces so that the timber is open at both ends, the gum exudes in small drops and thin pieces which dry very quickly. A cake obtained from draining a severed log was at first exceedingly tough, but after two or three months' exposure to the air, fractured between the fingers with a bright fracture. The gum is odourless and dissolves partially in cold water with a deep orange-brown colour, leaving a bulky gelatinous residue. The ash is white.

The gum from *C. apetalum*, obtained by wounding or felling the tree, is similar to *C. gummiferum* gum; it, however, smells of and may be regarded as an available source of coumarin, which is also plentiful in the bark. This gum swells considerably in cold water, to which it imparts a pale orange-brown colour and the coumarin odour. The ash is dark brown, bulky, and difficult to ignite; it contains a large proportion of manganese but only a little iron.

The *ceratopetalum* gums are astringent and may be described as kinos or kinoid gums; they resemble ruby kinos in colour and texture but differ from them by swelling up and being only partially soluble in water. Definitions of kinos take cognisance of tannic acid but do not allude to any gummy constituents, and if applied in this case would be the first instance of kinos being recorded from the *Sarifrageae*. However, in the kinos of *Eucalyptus* known to the author, all the gum is present as arabin, whereas the gum in the case of the *ceratopetalum* is present as metarabin; this is suggested as a possible objection to their being regarded as kinos, but in any case they form a connecting link between the kinos and metarabin gums and are a remarkable group. The composition of the gums is as follows:—

	<i>C. gummiferum</i> .	<i>C. apetalum</i> .
Tannic acid (estimated as gallotannic acid)	16·76	6·33
Phlobaphenes (soluble in alcohol)	19·5	12·21
Phlobaphenes (insoluble in alcohol together with metarabin).	41·6	52·00
Coumarin.....	Absent	{ Variable 2 to 3
Accidental impurity	2·5	2·0
Moisture.....	16·7	20·47
Ash.....	1·8	3·44

The residue from the treatment of *ceratopetalum* gums with water consists almost entirely of phlobaphenes and metarabin, the former in largely preponderating proportions; in fact by boiling with water to begin with the numbers for tannic acid in gums of this genus would be returned at between 40 and 50 per cent.; actual experiment gave 49·78 in *C. gummiferum*; 41·14 in *C. apetalum*. Owing to the difficulty of separating the phlobaphenes insoluble in alcohol from the metarabin, entirely satisfactory results have not been obtained in that direction, but from various experiments and observations, the conversion of the phlobathene into

tannic acid, and the metarabin into arabin, the physical appearance of the gums in water and in alcohol, &c., the author estimates the metarabin present at about 8 to 10 per cent.—D. A. L.

PATENTS.

An Improved Knife for Slicing Sugar Beets, Sugar Canes, and the like. R. Bergreen, Bitterfeld, Germany. Eng. Pat. 20,573, December 21, 1889. 8d.

THE knife is provided with a toothed or saw edge, and is fixed on an iron plate which may be inserted in the cutting box of the machine used for the purpose of cutting such materials. The knife, machines, and various arrangements and combinations thereof, are described in detail with reference to drawings.—A. J. K.

An Improved Method of Saccharification of Amylaceous Materials. E. Carez and "La Société Générale du Maltose," Brussels, Belgium. Eng. Pat. 3606, March 6, 1890. 4d.

THE feculant or amylaceous material is treated before saccharification with either benzene, light petroleum oils, or bisulphide of carbon to dissolve out the fatty or oily impurities. The liquid is drawn off to decant the oil and the solvent used over again. As some of the solvent remains in the material under treatment, this is expelled by a current of steam or hot air, and the material is then saccharified by the usual process. By this means the amount of bone-black required for purification is greatly reduced and an improved product obtained.—A. J. K.

A New or Improved Method of Cleaning, Treating, or Preparing Kauri Gum for the Market. J. C. Firth, Auckland, New Zealand. Eng. Pat. 17,009, October 24, 1890. 4d.

Kauri gum has hitherto been prepared for market by scraping off the outer crust by hand. In the improved process revolving or reciprocating wire (preferably steel) brushes are used, followed by buffs or similar devices. The dust is removed by fans passed through a machine known in flour mills as a "purifier," and thus purified, the recovered finely divided gum being available for use being freed from worthless debris.—R. B.

XVII.—BREWING, WINES, SPIRITS, Etc.

Contributions to a Knowledge of the Bacteria occurring in Wort and Beer. A. Zeidler. Wochenschr. f. Brau. 1890, 7, 1214.

THE author finds that the bacterium known as *Bacterium termo* is quickly destroyed when alcoholic fermentation sets in. Also that the stability of pressed yeast is dependent upon the bacteria present in it. When fresh cells of the above wort bacterium occur in the yeast, it quickly decomposes, whilst it is fairly stable when only those bacteria are present which accompany fermentation. Pressed yeast is but little affected by the acetic ferment.—A. L. S.

On the Possibility of Economising Hops in Brewing. M. Issleib. Allgem. Brau. u. Hopfenzeit, 1890, 30, 2173.

AS a part of the aromatic oils of the hop are volatilised during the boiling of the wort, at the same time a large portion of the hop bitter is destroyed, the author proposes to extract the hop bitter by water, then distil off the essential oil, and add these at the conclusion of the boiling. A great saving in hops is said to be thereby effected.

—A. L. S.

Malt Analysis. F. Schwaackhöfer. Mitth. d. österr. Versuchsstat. f. Brau. u. Malz. in Wein, 1890, Heft. 3.

THE results of 152 analyses of malt made at the Austrian laboratory for brewing and malting from October 1887 to December 1889:—

Apparatus for Collecting for further Utilisation the Excess of Carbonic Acid Generated during the Manufacture of Beer. L. Haas, Rierbach-Zurich, Switzerland. Eng. Pat. 20,630, December 23, 1889. Internat. Conv. June 27, 1889. 8d.

THE carbonic acid generated in the casks is forced by its own pressure into a gas-holder.

The carbonic acid given off from the fermenting vessel is collected in bells suspended over the fermenting liquid and just dipping into it. The gas is drawn off by means of a pump and led into the gas-holder.

The carbonic acid in the gas-holder is drawn off and compressed into suitable receivers.—A. L. S.

New or Improved Process and Apparatus for Ageing Liquors. W. P. Thompson, Liverpool. From J. A. H. Hasbrouck, Plainfield, U.S.A. Eng. Pat. 667, January 14, 1890. 8d.

THE process consists in exposing the liquor in a state of spray at a temperature of 100° F. to the action of oxygen under a slight pressure.

The apparatus consists of a wooden barrel-shaped vessel, mounted so as to be capable of rotation about its longer axis. A coil of black tin passes through the vessel, through which steam may be passed. Inside the vessel are a number of wooden arms at right angles to each other, and having spoon-shaped hollows at each end. All the wood inside is charred.

To use the apparatus it is partly filled with new liquor, and oxygen admitted under a pressure of about 5 lb. per square inch. The vessel is then closed and revolved for some days, the temperature being kept at about 100° F., by the steam coil. As the vessel revolves, the arms with their spoon-shaped hollows agitate the liquor and expose it to the action of the oxygen. After a few days the oxygen becomes vitiated, and it is allowed to escape and fresh oxygen admitted. The process is then continued until the required age has been reached. The inventor finds that 25 days' treatment is about equivalent to a year's natural ageing.—A. L. S.

Improvements in Corn Product for Brewers' Use and in the Manufacture thereof. H. Bates, jun., Indianapolis, U.S.A. Eng. Pat. 16,951, October 23, 1890. 4d.

IN order to obtain maize in a condition suitable for brewing it is first hulled and degerminated. The corn is then placed in a tank of warm water, the water not being sufficiently hot to gelatinise the starch; the exact temperature and duration of soaking varies with the character of the corn; as a rule the temperature may be from 70–100° F. The granules, when sufficiently soaked, are crushed between cold rollers and then dried.—A. L. S.

An Improved Method of and Apparatus for Preserving Milk. E. Edwards, London. From A. Seidenstiecker, Wülfel, Germany. Eng. Pat. 19,281, November 30, 1889. 11d.

MILK is heated to and sustained at a temperature of 69° C. for 30 minutes or of 75° C. for 15 minutes, or during hot weather at 96° C. for 10 to 12 minutes in a tinned copper vessel previously sterilised by steaming, in which steam of suitable temperature is caused to circulate through three concentric coils of tinned copper piping, one near the periphery, the other two of smaller piping near the centre, vanes attached directly to and also to arms connected with a rotating central shaft keep the milk in agitation; the temperature, as indicated by a thermometer provided for the purpose, is regulated by shutting off or admitting steam. After sufficient exposure to the desired temperature the milk passes to a cooler, also previously sterilised by steaming where it is caused to flow over the outside of a corrugated cylinder through the interior of which a stream of cold water is circulating. The cool sterilised milk is then directly transferred to special sterilised cans for transport, furnished with a tightly-fitting cover provided with tubes passing inside to permit of steaming, one of which terminates just beneath the cover, whilst the other extends to the bottom of the can; when filled with milk the exterior openings of the tubes are closed hermetically by means of sterilised screw stoppers. All the apparatus here described is easily disconnected for cleansing purposes.

It is asserted that by this method milk may be preserved during several days, and that its natural flavour, odour, and appearance are retained.—D. A. L.

A New or Improved Alimentary Liquid. J. H. Hooker, Winslow, Bucks. Eng. Pat. 192, January 4, 1890. 4d.

MILK, peptonised or otherwise, and preferably with the cream removed, is boiled, cooled, and mixed with cane sugar or other saccharine matter—about 4 lb. per gallon—and with pure lime or lemon juice or the two mixed—about six fluid ounces per gallon—or an equivalent quantity of an innocuous, agreeably flavoured and suitable vegetable acid; alcoholic fermentation is induced by the addition of brewers' yeast—about two fluid ounces per three gallons of the mixture—and the fermented liquid fined by means of isinglass or otherwise, is stored in wooden casks and treated in the same way as ordinary wine.—D. A. L.

Improvements in the Method of Producing Infusions of Tea and similar Solutions Free from Tannin. H. Grimshaw, Manchester. Eng. Pat. 982, January 20, 1890. 4d.

THE tannin present is absorbed by means of suitable animal substances, such as horn shavings, dried albumen, hide clippings, and the like. It is preferable to add the material to the tea in the dry condition before the infusion is made.

But it may, also, be added to the infusion or the infusion may be passed or filtered through a layer of the substance. The quantity of animal substance to be added to the tannin-containing material must be determined by the amount of tannin contained in it. In the case of tea the proportion may vary from one to two parts of animal substance to ten parts of tea.—B. H.

Treatment of Press and Extraction Residues of Oil Manufacture for obtaining Valuable Products therefrom. H. Noerdlinger, Stuttgart, Germany. Eng. Pat. 1109, January 21, 1890. 6d.

IN the production of oils, by-products consisting of oil-cakes or oil-cake meals are obtained. These on account of the high percentage of fatty acids are, notwithstanding their great wealth of nutritious elements, only suited for horse and cattle food. The object of the inventor is to obtain food-substances suitable for human consumption.

The fat is—

Rapeseed cake contains about 10 per cent. of free acid.			
Palm-nut cake	"	14½	" "
Coena-nut cake	"	16½	" "
Earth-nut cake	"	18	" "
Sesamé cake	"	41	" "
Poppy-seed cake	"	51	" "

The cake is extracted by means of alcohol. Strong alcohol is employed to dissolve the fatty acids and some of the sugar; when it is desirable to dissolve more sugar, weaker alcohol is used. When only sugar is to be extracted water is chosen as a solvent. From the alcoholic solution the sugar and fatty constituents are separated by distilling off the solvent, when the sugar-syrup sinks to the bottom and the fatty constituents float on the top. The latter may be used for the manufacture of soap and the lixiviated cake forms a meal very rich in nitrogenous substances which is suitable as food for those suffering from diabetes. By well-known mechanical treatment the coarse-grained particles of indifferent flavour may be separated from the fine-grained meal of good flavour. The latter contain about 50 per cent. of protein compounds.—K. E. M.

(B.)—SANITARY CHEMISTRY.

Fluorides as Agents for Softening Waters. C. A. Doremus, J. Amer. Chem. Soc. 1890, 12, 303.

SODIUM fluoride has been found, by experiments made in the laboratory on a somewhat large scale, to be an excellent softening reagent. The magnesium compounds are completely precipitated by its use.

Other fluorine compounds may also be employed for the same purpose. No patents seem hitherto to have been taken out for their commercial use. They possess advantages over lime, soda-ash and caustic soda.—P. J. H.

On the Use of Galvanised Iron for Artesian Wells and for the Conveyance of Drinking Water. R. Haines, J. Franklin Inst. 1890, 100, 333—401.

THE author analysed a sample of water from an artesian well, recently sunk, 78 ft. deep, of which both the outer and inner casing were made of galvanised iron. There was no source of sewage contamination near the well, yet its composition showed per 100,000 parts 0.473 parts free ammonia and 0.008 albuminoid ammonia, only faint traces of nitrates being present, but there was a large amount of zinc in solution. The solids consisted of:—

	Grains per Gall.
SiO ₂ , Al ₂ O ₃ , and Fe ₂ O ₃	0.85
NaCl	0.77
CaCO ₃	1.30
(NH ₄) ₂ CO ₃	1.25
ZnCO ₃	6.52
Total solids	10.69

The analysis shows that the free ammonia has evidently been increased by reduction of nitrates of iron and zinc, and that the water undoubtedly had been previously contaminated by animal sewage.

On heating the sample the zinc separated out as a film on the surface. The author considers that the oxide and carbonate of zinc have combined with the ammonium carbonate to form the double zinc and ammonium carbonate, which is insoluble in water, but very soluble in ammonium carbonate, the excess of ammonium carbonate in the water holding it in solution. This combination of salts is decomposed on heating.

Experiments showed that commercial zinc and chemically pure zinc were rapidly acted on by a cold dilute solution of ammonium carbonate, which after 24 hours' contact gave a copious precipitate with sulphuretted hydrogen on acidifying with acetic acid.

Zinc not being so accumulative as lead, is less injurious to health, and, as is also known, zinc is contained in small quantities in some drinking waters in use.

The author concludes that while under the usual conditions of water supply galvanised iron piping may be used, yet too much confidence should not be placed in it. All the conditions under which this piping is to be used should be carefully considered, including a chemical analysis of the water; and, in the presence in the water of considerable amounts of certain saline substances, such as ammonia salts, chloride of sodium and nitrates, as well as very small amounts of free mineral acids, &c., galvanised iron should not be used at all. Under such circumstances, only pipes coated with a non-metallic interior surface should be used.

—D. A. S.

PATENT.

Improvements in and in the Preparation of Material for Use in the Treatment of Sewage and other Polluted Water and Liquids. F. P. Candy, Baltham. Eng. Pat. 16,972, October 24, 1890. 4d.

Iron sulphate partially decomposed by heat "so as to form a mixture of oxide, protosulphate, and persulphate of iron, together with a proportion of Nordhausen sulphuric acid" is either exposed to the atmosphere to "weather" or subjected to the action of moist air or steam in a closed chamber; "the mass regains constituents lost in the roasting operations, and is then in a state for use" by adding it in any form and in any desired proportions to the liquid sewage or impure water.—D. A. L.

(C.)—DISINFECTANTS.

PATENTS.

Improvements in the Treatment of Hemp, Flax, Jute, Cotton, and other Substances in order to Preserve the Same. F. T. Truman, London. Eng. Pat. 19,773, December 9, 1889. 4d.

See under A., page 133.

Improvements in the Manufacture of Sheep Dip. G. Craig, Dalry. Eng. Pat. 889, January 17, 1890. 4d.

This invention relates to the class of dips consisting of combinations of phenols (phenol, cresol, xylenol, and their homologues) with alkali and sulphur. Suitable crude oil derived from the tar of gas works, blast furnaces, coke ovens, or gas producers, is agitated with a compound of alkali and sulphur, preferably an alkaline polysulphide, heat is applied, and after settling, the compound of phenols, alkali, and sulphur is separated from the supernatant oil, and may be further treated until of desired quality.—D. H.

Improvements in the Manufacture of Disinfectants, Antiseptics, Deodorants, Insecticides, and Sanitary Reagents. C. T. Kingzett. Eng. Pat. 1589, January 29, 1890. 4d.

Oxidised turpentine is rendered less inflammable, miscible with water, and suitable for general application as a disinfectant, &c. by mixing with soft or hard soap; good proportions being 2 cwt. of the former to 94 gallons of the oxidised oil, whilst of the latter 84 lb. are dissolved in 50 gallons of the oxidised turpentine at about 60° C.

—D. A. L.

Improved Insect Destroyer and Manufacture of the same. W. P. Thompson, Liverpool. From P. Leonardi, P. Zeni, and G. Sardi, Venice, Italy. Eng. Pat. 17,256, October 28, 1890. 4d.

An insecticide or entomophobe is prepared by extracting chrysanthemum or pyrethrum with alcoholic potash, soda, lime, or preferably ammonia, and digesting with ether, essence of turpentine, benzine, paraffin, wax, olive oil, fatty substances, or other suitable hydrocarbons. Or the chrysanthemum is simply treated with an alkaline nitrate or with ammonia extracted with water, and the ammonia expelled or neutralised. The preparation, either as a spray, or strewn about, or burnt in candles, lamps, &c., or mixed with a nitrate, &c. and made into capsules for burning, may be employed as a general insecticide in rooms, fields, orchards, &c.—D. A. L.

XIX.—PAPER, PASTEBOARD, Etc.

On the so-called "Sulphite Lye," and on the Rotation of Gluconic, Galactonic and Rhammonic Acids. F. Weld, J. B. Lindsay, W. Schuelle, and B. Tollens. Ber. 23, 2990—2992.

In the manufacture of sulphite cellulose, a solution is obtained in which mannose and galactose are found. This "sulphite lye," in addition to gypsum and calcium sulphate, contains much organic matter, and, if distilled with sulphuric or hydrochloric acid, furfural or furfuralamide are obtained, hereby proving that penta-glucoses or pentoses (xylose) are present in "sulphite lye." When this liquid, mixed with sulphuric acid, is treated by hydrolysis, then neutralised, concentrated, freed from gum, and phenylhydrazine acetate added, a hydrazone compound is obtained, corresponding to mannose-hydrazone which, when freshly prepared, is for a short time levo-rotatory. When the liquid is evaporated, and the residue heated with nitric acid, precipitates are obtained from which nucleic acid can be extracted, hereby proving that galactose compounds are met with in "sulphite lye." The presence of saccharic acid could not be proved, but vanillin was found by means of the phloroglucinol reaction.

The acids obtained by oxidation from glucoses possess a remarkable kind of bi-rotation, as the following table shows:—

	1.	2.	3.	4.
	(a) ₁ in Freshly Prepared Solutions.	(a) ₂ a Week or more Afterwards.	(a) ₃ when the Fresh Solutions are heated on the Water-Bath for Half an Hour.	(a) ₄ a Week or more after No. 3.
Gluconic acid.	+ 2° 53	+ 9° 8 to 10° 4	+ 19	+ 9° 5
Galactonic acid.	- 10° 56	- 16° 82	- 57° 84	- 53° 36
Rhammonic acid.	- 7° 67	- 29° 21	- 31° 30	- 30° 12

PATENTS.

An Improvement in Coating Iron, Steel, or other Metal with Lead. J. Makin, Glossop. Eng. Pat. 14,071, October 24, 1884. (Second edition.) 6d.

An Improved Compound Lining for Boilers or other Vessels Used in the Manufacture of Paper Pulp from Wool or other Vegetable Fibre. J. Makin, Belfield. Eng. Pat. 5626, May 7, 1885. (Second edition.) 6d.

BOILERS of wrought iron or steel, lined with lead, are usually used for boiling wood, &c. with strong acid or corrosive solutions in paper pulp manufacture. To support the lead and to check its propensity to "creep," sheets of iron or other hard metal, perforated with cylindrical or conical holes, are placed in a mould suitably prepared; and on one or both sides coated with lead, applied in a molten state. The boilers lined with such plates resist the action of the heated acids and corrosive substances much better than when lined with lead in the ordinary way.—H. S.

An Improved Film or Skin. J. Williams, Willesden Junction. Eng. Pat. 20,524, December 20, 1889. 4d.

PAPER is floated on a solution of euprammonium hydroxide. Hereby one surface of the paper is converted into a jelly-like cupra-cellulose which is dried, and the film thus obtained, separated from the paper by disintegrating the latter with boiling water, the pulp being removed by a stream of water or by revolving brushes. Then the film is dried by being passed round warm cylinders. If treated with dilute acids the film becomes white. The film thus obtained possesses the properties of fine paper, and is capable of resisting the action of water, steam, weak acids, alkalis and most solvents.—H. S.

An Improved Method of Manufacturing Rods of Parchmentised Fibre. R. P. Frist, Wilmington, U.S.A. Eng. Pat. 5841, April 17, 1890. Internat. Conv. February 13, 1890. 6d.

CYLINDRICAL bars or rods of parchmentised fibre cannot be obtained by turning in a lathe, as the material springs. The inventor therefore proposes to use a tool consisting of a hollow stem or mandrel, having at its front end four cutting blades which reduce square or polygonal rods to a cylindrical form, whilst the rod continues to pass through the centre of the mandrel.—H. S.

Improvements relating to Apparatus for Boiling Wood-Pulp. F. V. L. Hirth, Christiania, Norway. Eng. Pat. 15,995, October 8, 1890. 6d.

This invention relates to an arrangement for connecting together a number of wood-pulp boilers for the purpose of utilising the gas and heat which are evolved during the process of boiling.—E. J. B.

Improvements in Agitators for Stuff Chests Used in the Manufacture of Paper. H. H. Lake, London. From M. D. Currier, Massachusetts, U.S.A. Eng. Pat. 16,796, October 21, 1890. 6d.

THE improvements consist in the employment of blades of peculiar construction attached to a revolving shaft in the centre of the stuff chest. By means of these blades a more perfect circulation of the pulp is attained, and consequently a more intimate mixing of its various constituents.—E. J. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Concentrated Essential Oils of Lemons, Limes, &c.
A. A. Barrett.

See pages 106–108.

Crystalline Constituents of Semen Cataputivæ minoris.
Yoshisumi Tahara. Ber. 23, 3347–3351.

THE seeds of *Euphorbia lathyris*, which are still used to some extent for medicinal purposes in Japan, contain asculetin and another crystalline compound which melts at 193°; the asculetin can be isolated as follows:—The crushed seeds are freed from oil by pressing extracted with boiling 90 per cent. alcohol, and the solution evaporated; the residue, which consists of a brown solid and an oil, is freed from the latter by washing with ether, then extracted with small quantities of cold water and dissolved in boiling alcohol; on cooling the asculetin is deposited in brown crystals. It can be purified by repeated recrystallisation from boiling water, with addition of animal charcoal, or by treating the alcoholic solution with lead acetate; in the latter case the precipitated lead compound is washed with alcohol and water consecutively, then decomposed with glacial acetic acid, and the undissolved asculetin recrystallised from boiling water. The yield is about 0.9 per cent. of the seeds employed.

The identity of the asculetin obtained in this way with that formed by the decomposition of the glucoside, asculin, was proved by a number of experiments.

The compound melting at 193° referred to above is deposited in colourless crystals when the clear oil of the seeds is kept for a long time in closed vessels; it is odourless and insoluble in water, but readily soluble in hot alcohol and other organic solvents. Owing to lack of material it has not yet been further examined.—F. S. K.

The Etheral Oil of Asafetida. F. W. Semmler.
Ber. 23, 3530–3533.

HLASIWETZ has shown that the etheral oil of *Asafetida* contains hexenyl sulphide and hexenyl disulphide (Ann. Chem. Pharm. 71, 23), and that it is one of the few etheral oils found in nature, which contain sulphur and no nitrogen.

Two samples of the oil were examined, which were found on analysis to contain 3.29 per cent. and 3.04 per cent. of oxygen respectively, the presence of which has previously been overlooked. When fractionated in vacuo the crude oil yields four products, boiling as follows under a pressure of 9 mm. :—

	Boiling Point.
Fraction I.	65°
Fraction II.	80°–85°
Fraction III.	120°–130°
Fraction IV.	133°–145°

These fractionations as obtained from the two samples examined differed both as regards specific gravity and percentage composition, but nevertheless the two samples appear to contain the same constituents though in different proportions.

When the oil is treated with metallic sodium in vacuo until there is no further evolution of gas and then distilled, a mixture of two terpenes ($C_{10}H_{16}$) results, the specific gravity of which is 0.8602 at 10° C. When treated with bromine one of these yields a liquid dibromide, the other a solid tetrabromide. The fourth fraction is also obtained in small quantity when the crude oil is distilled under the ordinary pressure. A dark blue oil passes over at 268°, which has a specific gravity of 0.9636 at 22° C., and is laevo-rotatory. This product, when treated with sodium in vacuo and then distilled, yields a sesquiterpene, $C_{15}H_{24}$, which consists of a colourless oil boiling at 256°, and combining with hydrochloric acid to form a hydrochloride, $C_{15}H_{24} \cdot 2 HCl$.

Fractions II. and III., obtained as above, consist of the sulphur-containing constituents of the oil, from which the latter derives its unbearable smell. These products are under investigation.—C. A. K.

The Alkaloids of Belladonna. O. Hesse. *Annalen*, **261**, 87—107.

This contains a résumé of the work done on the belladonna alkaloids followed by results recently obtained by the author, who has discovered a new alkaloid, which he names *atropamine*. This may be obtained from the crude alkaloid extracted from belladonna root by adding common salt to the solution in acetic acid, or when the atropamine is present only in small quantity the atropine is first separated, and the alkaloids from the mother-liquor dissolved in acetic acid, and salt added; atropamine hydrochloride crystallises out, and may be purified by recrystallisation from boiling water. The free base, obtained by agitating the hydrochloride with dilute ammonia and ether and subsequent evaporation of the ethereal solution, forms a colourless varnish-like mass; at about 60° it is a clear colourless, odourless, mobile liquid. It does not lose in weight at 100°, its composition agreeing with the formula $C_{17}H_{21}NO_2$. It dissolves very readily in ether, chloroform, alcohol and benzene, sparingly in light petroleum and water; its alcoholic solution has no rotatory action on polarised light, no action on phenolphthalein paper, but turns red litmus blue. Several of its salts are described. Atropamine differs from the other belladonna alkaloids, atropine, hyoscyamine and hyoscyne, in that it has no mydriatic action, and it also differs from apatropine, in producing a burning sensation and inflammation when dropped into the eye, apatropine being inactive.

Belladonnine has the same empirical formula, $C_{17}H_{21}NO_2$, as atropamine, and is obtained from the latter by exposing to sunlight atropamine hydrochloride moistened with hydrochloric acid; by evaporating a solution of the sulphate; by dissolving the alkaloid in cold concentrated sulphuric acid; by boiling with baryta-water, hydrochloric acid or dilute sulphuric acid. The best method is to heat atropamine hydrochloride with fairly concentrated hydrochloric acid at 80°. Belladonnine forms a colourless varnish-like substance, is readily soluble in ether, alcohol, chloroform, and benzene, sparingly in light petroleum and in water; it forms salts which are however amorphous.

When atropamine is boiled with baryta-water or moderately concentrated hydrochloric acid, it is first converted into belladonnine, this then undergoing a further change, so that the same decomposition products are obtained from both atropamine and belladonnine. The products isolated by the author are a base, $C_{15}H_{19}NO$, and two amorphous acids, $C_8H_9O_3$ and $C_8H_9O_2$. The base has been identified by means of its platinumchloride and anisochloride, and found to be identical with pseudotropine, and not with tropine as stated by Merling (*Ber.* **17**, 383). The formation of these products is indicated thus:—

When atropamine is heated at 100° with fuming hydrochloric acid a crystalline acid is mainly produced in the place of the above mixed amorphous acids, pseudotropine being also obtained as in the first case. The crystalline acid melted at 107°, and proved to be atropic acid; its formation may be expressed thus:—

Atropamine, like hyoscyne, is not a constant constituent of belladonna. It could not be detected in cultivated belladonna, nor in the leaves of the wild plant, whilst the roots of the latter usually contain but traces. In one sample, however, of a root of unknown source a considerable quantity of atropamine was found. Its occurrence appears to be confined to the roots. The cultivated belladonna plant contains solely atropine, which is also obtained in a somewhat less pure condition from the leaves of the wild plant, and in smaller quantity also from the roots. An old belladonna root was found to contain a good deal of hyoscyamine, but no atropine.—A. K. M.

The Indian Grass Oils. F. D. Dodge. *Amer. Chem. J.* **1890**, **12**, 553—564.

CITRONELLIC aldehyde, $C_{10}H_{18}O$, the principal constituent of oil of citronella, is a colourless oil, apparently unaltered by exposure to light or by long standing in a closed vessel, but readily oxidising on exposure to the air (this *Journal*, **11**, 456). Its specific gravity at 20° C. is 0.8560, and its rotatory power (α_D) = + 4.50°. It has a specific refraction 0.3091, whence the molecular refraction, $R_M = 47.60$, is calculated. The latter agrees with the open chain formula $C_4H_9-CH=CH-C_5H_9-COOH$, whence the aldehyde appears as a member of the acrolein series— $C_nH_{2n-2}O$. The bromine addition product of the aldehyde decomposes on heating with the formation of eymene; citronellie aldehyde when treated with iodine and the product of the reaction distilled, yields no eymene, but a hydrocarbon boiling at 160° which has not yet been identified.

Phosphoric anhydride acts upon citronellie aldehyde in moist ethereal solution with the formation of a strong acid which contains phosphorus. It is the (COH) group of the aldehyde that appears to take part in this reaction, which only takes place in presence of water. The new acid is a crystalline body, melting near 203°, sparingly soluble in water, readily in alcohol, and with difficulty in ether. It is moderately stable in presence of aqueous acids, but is decomposed by warm alkalis with the formation of an oil which has not been further examined. The sodium, potassium, and ammonium salts of the acid, which is monobasic, are crystalline and readily soluble; the sodium salt is the least soluble of the three. The salts with aniline and with quinoline are also crystalline; the former consists of white needles, melting at 165°. The acid is optically active in solution. Its most obvious formula is—

Attempts to obtain analogous compounds with other aldehydes (cinnamic aldehyde, benzaldehyde, cinnanthaldehyde) were unsuccessful.

Lemon Grass Oil, like citronella oil, contains a peculiar aldehyde. The sample examined was a Ceylon oil, which, when redistilled, possessed a light yellow colour and the characteristic odour of the lemon verbena. Its specific gravity at 22° C. was 0.866. The chief fraction of the oil boils at 220°—225° and it reacts with ammoniacal silver nitrate solution, phenylhydrazine, and acetyl chloride just like citronella oil. The action of acid sodium sulphite is peculiar. When an excess of the sulphite is added to the oil, a crystalline molecular compound is first formed, which on standing goes completely into solution. This solution can be concentrated at 100°, when it shows signs of supersaturation, and on being agitated, solidifies to a crystalline mass which contains 52.9 per cent. of water and appears to be a complex acid sulphite. It differs, however, from the generality of these compounds in the fact that the aldehyde is liberated by the addition of alkalis, but not by that of acids. The aldehyde forms a light yellow liquid, boiling with gradual decomposition about 225°; an analysis points to the formula $C_{10}H_{16}O$, hence it is isomeric with eumphor. The name *citridic aldehyde* is proposed for the new body, the physical properties of which the author has not been able to investigate accurately, owing to the product obtained not being sufficiently pure. The bromine addition product of the aldehyde is unstable. Phosphoric anhydride acts upon the aldehyde with the formation of para-methyl propyl-benzene (eymene) in small quantity; concentrated hydrochloric acid acts more readily and yields 50 per cent. of eymene. On reduction with zinc and acetic acid the aldehyde appears to yield an alcohol; on oxidation with dilute potassium permanganate a mixture of acids results in which neither acetic nor valeric acids could be detected.

A portion of the lemon grass oil does not enter into reaction with acid sodium sulphite, and this probably contains a terpene and eymene.

Indian Geranium Oil contains as its chief constituent *geraniol*, $C_{10}H_{18}O$, which on distillation yields a terpene,

geraniene, $C_{10}H_{16}$, an optically inactive body, boiling at 162° — 164° , which forms a liquid hydrochloride, but no hydrate. Geraniol readily absorbs hydrochloric acid gas to form geranyl chloride, $C_{10}H_{17}Cl$, a yellow oil of peculiar aromatic odour, which decomposes on heating and does not solidify at -15° . A sample of Ceylon ginger-grass oil examined gave as the chief fraction a product boiling at 227° — 233° which appears to be identical with geraniol.

In view of Semmler's investigations on Indian geranium oil (this Journal, 1890, 889), the author has suspended his experiments on this subject.—C. A. K.

Antipyrine Valerianate. Soehaczewski. L'Union pharmaceutique, 1890, **31**, 516.

ANTIPYRINE valerianate forms white cubical crystals, soluble in water. It has not a specially unpleasant taste; it has a more powerful physiological action than antipyrine. A double valerianate of antipyrine and quinine forms prismatic needles, readily soluble in water and alcohol. It resembles quinine valerianate in taste and smell, and has a very marked action in cases of neuralgia in the head and of intercostal neuralgia.—C. A. K.

Methylal as an Extractive. Chem. Zeit. **14**, 1474.

METHYLAL possesses the advantages of a low boiling point, and very ready volatility for extracting the odoriferous principles of plants, and has been employed with some success in the case of violets.—C. A. K.

PATENTS.

An Improved Process for Producing Ozonised Oils. F. Pickenbroek, Berlin, Germany. Eng. Pat. 4137, March 17, 1890. 4d.

WHEN ozonised oxygen is passed through fat and dry oils, the ozone is absorbed to a large extent, whilst the oxygen escapes. Such ozonised oil possesses greater strength than ozone water, as the oil is a better solvent for ozone, and may be used with greater advantage for cosmetical and technical purposes.—K. E. M.

An Improved Method of and Apparatus for Extracting and Purifying Perfumes, Oils, and other like Substances. H. H. Lake, London. From "La Société Anonyme des Parfumes Naturels de Cannes," Paris, France. Eng. Pat. 5940, April 18, 1890. 1s. 3d.

THIS invention relates mainly to mechanical improvements, which are given in detail, and which cannot be adequately described without reference to the drawings.—K. E. M.

Improvements in Means or Apparatus for Producing a Flash Light, more especially applicable to Photography. T. H. Redwood, Chingford. Eng. Pat. 401, January 9, 1890. 8d.

A FLAME of alcohol, gas, or other combustible material is allowed to play against a screen of sheet metal or wire gauze, so that it is spread out over a considerable area. A charge of magnesium powder is blown from a tube into the flame, the powder first striking a curved piece of metal, by

which it is spread more or less uniformly over the surface of the flame. Under these circumstances combustion is more perfect than in magnesium flash-lamps in which the metal is blown into a flame in a concentrated jet.—C. H. B.

New or Improved Method of and Apparatus for Ascertaining the Requisite Time of Exposure in Photography. E. G. Ballard, Chester. Eng. Pat. 669, January 14, 1890. 11d.

AN instrument for measuring the relative intensity of the photographically active rays reflected from any landscape or other object by observing the time required for the light from a phosphorescent compound to fade from its maximum intensity to the intensity of the light reflected from the object. It consists of an opaque tube with an eye-piece at one end, whilst at the other is a plate of glass, part of which is coated with Balmain's paint, or some similar phosphorescent substance emitting only rays which act upon an ordinary photographic plate. The paint must either be opaque or must be made opaque by means of a backing. Behind this glass is a piece of ground glass, and there may also be a piece of blue glass cutting off from the light reflected from the object all rays except those which act on a photographic plate. The frame carrying these glasses is hinged, so that it can be turned back in order to expose the phosphorescent substance to light. When a measurement is to be made, the frame is turned back, and the phosphorescent surface is exposed to daylight or to the light from burning magnesium, for a time sufficient to excite the maximum luminosity. It is then put back in position, and the apparatus is at once directed towards the object to be photographed. The light reflected from this object passes through the unobstructed portion of the ground glass and blue glass, and at first appears dark as compared with the light from the phosphorescent surface. The brightness of the latter, however, gradually fades, until the two lights are equal in intensity. The time required for this to take place is observed, and with this datum and a series of tables supplied with the instrument, the exposure necessary to obtain a good photograph of the object in question is ascertained.—C. H. B.

A Scarlet Liquid for the Treatment of Negatives in the Art of Photography, by Means of which Liquid Clouds can be made and many other Useful and Artistic Effects produced. H. H. Beale, Reading. Eng. Pat. 16,238, October 13, 1890. 6d.

A TRANSPARENT scarlet solution, which the author calls "non-actinic," and which is used for blocking out skies, strengthening shadows, working in clouds, and otherwise improving photographic negatives. It does not dry very rapidly, and hence lends itself to modification, such as softening off the edges, &c., after it has been applied to the glass. When once dry it withstands the ordinary wear and tear to which a negative is subjected, but can be removed by treatment with water. The preparation is usually applied to the back of the negative, but may also be put on the face of the film, provided that the latter has not been varnished.

375 grains of good gelatin are cut into pieces, and allowed to soak for several hours in 1 pint of pure (not necessarily distilled) water. It is then melted by the application of a gentle heat, and 150 grains of good aniline red, 75 minims of prepared ox-gall, and about 10 drops of creosote are added. When all the materials are thoroughly mixed the liquid is strained and bottled.—C. H. B.

Improvements in Photographic Films. A. J. Boulton, London. From G. Eastman, Rochester, U.S.A. Eng. Pat. 19,658, December 2, 1890. 8d.

FILMS composed of nitrocellulose, camphor, and other substances, and coated with gelatinobromide emulsion, bulge and buckle owing to the greater contraction at the edges, a result believed to be due to the evaporation of the solvents. If, however, the film is protected by coating it on both sides with a "sealing coating" of gelatin or similar material, the

contracting and buckling is almost completely prevented. The back sealing coating is preferably of translucent or transparent gelatin made insoluble by the addition of a suitable quantity of chrome alum. The front coating may be of the same kind, but the sensitive gelatinobromide emulsion itself answers the same purpose. One method of preparing the film is to coat a waxed glass plate with gelatin mixed with chrome alum, and when this is dried it is flooded with the solution of nitrocellulose and camphor. As soon as the solvents have evaporated, and the film is dry, it is coated with sensitive gelatinobromide emulsion, dried in the usual way, and stripped from the glass. The film support may be made without camphor, and with substitutes for the nitrocellulose; the gelatin may be replaced by albumen made insoluble in water when dried, and the precise method of coating and stripping the films may be varied.—C. H. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

On the Determination of the Strength of Various High Explosives. W. Walke (Instructor in Charge U.S. Artillery School Laboratory). J. Amer. Chem. Soc. 1890, 12, 256–274.

The author has compared the action of a number of "high" explosives with that of nitroglycerin on the Quinan pressure-gauge. The apparatus consists of (1) a heavy cast-iron base, into which is let a steel plate flush with its upper surface; (2) a piston of tempered steel, 1 in. in diameter and 5 in. in length (12½ lb. in weight) moving freely up and down between four vertical wrought-iron guides fixed into the iron base at points on a circumference 1 in. in diameter; in the top of the piston is a cavity in which the explosive is placed; (3) a shot of tempered steel 1 in. in diameter, 10 in. in length, weighing 31½ lb., and bored through the axis to receive a capped fuse. In testing an explosive, a cylinder of lead is placed between the piston and the steel plate, the explosive is put into the head of the piston, the shot lowered gently over it, the fuse inserted and fired from the cap. When the charge explodes the shot is thrown out and the lead crushed. Quinan determines the number of foot-pounds necessary to produce different amounts of compression and plots a curve with foot-pounds as abscissa and compressions as ordinates in order to determine the work done which corresponds to a given compression; he assumes the "strength" of the explosive to be measured by this amount of work. The author was unable to use the instrument in this way, and has only measured the compressions produced. He thinks the results given by the gauge are trustworthy in the case of "high" explosives, i.e., those in which the reaction takes place very rapidly, but it is practically useless for slower explosives.

Lead of a uniform quality was obtained and was made into cylinders 1 in. in diameter, 1 in. in height, and having a mean weight of 145.729 grms., the differences in weight between different cylinders not exceeding 10 to 15 mgrms.

The standard nitroglycerin was made by mixing two parts of HNO_3 (sp. gr. 1.50) with four parts H_2SO_4 (sp. gr. 1.84), cooling and then adding to the mixture with constant agitation 1 part of chemically pure anhydrous glycerin. After total conversion into the nitric ether, the latter was freed from all traces of acid, poured into a glass jar, covered with distilled water and left for six weeks until it became quite transparent and in appearance exactly similar to pure glycerin. The nitroglycerin varies in strength from day to day until this stage is reached, but it then possesses permanent properties.

The weight of explosive taken as the charge was in all cases 24 grams (1.555 grms.). A full record of the mode of preparation of each explosive, and of the separate experiments is given; they are summarised in the following table.

The diminution in the height of the cylinder produced by nitroglycerin being called 100, the ratio of the diminution produced by any other explosive to this diminution is given under the column "Order of Strength."

Name of Explosive.	Diminution in Height of Cylinder, expressed in inches.	Order of Strength.
1. Explosive gelatin made from nitro-glycerin after the Vonges process.	0.585	106.17
2. Hellhofite	0.585	106.17
3. Nitroglycerin (made Nov. 19, 1889, tested Jan. 6, 1890).	0.551	100.00
4. Nobel's smokeless powder.....	0.509	92.38
5. Nitroglycerin (made Jan. 29, 1890, tested on same day, U.S.N. Torpedo Station process.).	0.509	92.38
6. Explosive gelatin (made from nitro-glycerin No. 5).	0.490	88.93
7. Gun-cotton (U.S.N. Torpedo Station, 1889).	0.458	83.12
8. Gun-cotton (Stowmarket, 1885)	0.458	83.12
9. Nitroglycerin (made according to the French process and tested on the same day).	0.451	81.85
10. Gun-cotton (made in Artillery School Laboratory).	0.448	81.31
11. Dynamite No. 1	0.448	81.31
12. Dynamite de Triauzel	0.437	79.37
13. Emmensite.....	0.429	77.86
14. Amide powder.....	0.385	69.87
15. Oxonite (peric acid fused before being added).	0.383	69.54
16. Tente	0.376	68.24
17. Bellite	0.362	65.70
18. Oxonite (peric acid not fused).....	0.354	64.24
19. Rack-a-rack.....	0.340	61.71
20. Atlas powder.....	0.333	60.43
21. Ammonia dynamite	0.332	60.25
22. Volney's powder, No. 1.....	0.322	58.44
23. Volney's powder, No. 2.....	0.294	53.18
24. Melinite	0.280	50.82
25. Silver fulminate.....	0.277	50.27
26. Mercury fulminate.....	0.275	49.91
27. Mortar powder, Dupont.....	0.155	28.13

The author has confirmed his table of orders of strength by actual measurements of the amount of work done by quantities of substance proportional to the number in the third column (details not given). He considers that his experiments dispose of the claims put forward for newly invented explosives, said to be "stronger" than nitroglycerin, though they may be made capable of doing "more mechanical work" by the admixture of some foreign inert ingredient, or change of physical state. He quotes an official report of Professor C. E. Munroe, which points out "that 1 lb. of pure nitroglycerin was found to exert only 81 per cent. of the intensity of action of ¾ lb. absorbed by an inert substance (kieselguhr) which can add nothing to the heat or gases developed."—P. J. H.

New Application for Calcium Plumbate. G. Kassner
Chem. Ind., 1890, 13, 392–393.

Calcium plumbate is recommended as a substitute for lead peroxide in paste for tipping matches, inasmuch as it offers many advantages. Firstly, in it the lead peroxide is more intimately mixed and distributed, and is consequently more active, than in the uncombined state; then the highly basic

character of the lime comes into play, and, promoting combination with the acid products of combustion, reduces objectionable fumes; again, the cementing property of lime is evinced when moistened calcium plumbate is exposed to the air, so that a match paste containing it "sets" to a certain extent of its own accord, and so requires less of, and results in a saving in, the ordinary cementing materials employed. Finally, its cheapness is regarded as the greatest advantage, made as it is with utmost facility by merely heating a mixture of lime and lead oxide in a muffle with free access of air. (See also this Journal, 1890, 187.)

—D. A. L.

The Preparation of Cotton-Waste for the Manufacture of Smokeless Powder. A. Hertzog. Centrbl. f. Textil. Ind. 1890, 21, 975.

THE military authorities require a cotton which, when thrown into water, sinks in two minutes; when nitrated, does not disintegrate; when treated with ether, yields only 0.9 per cent. of fat; and containing only small traces of chlorine, lime, magnesia, iron, sulphuric acid, and phosphoric acid. The waste from the spinning machines and the looms is boiled with soda-lye under pressure, washed, bleached with chlorine, washed, treated with sulphuric or hydrochloric acid, washed, centrifuged, and then dried. When the cotton is very greasy it is first boiled with lime-water. The loss in these treatments varies largely; for example:—Moisture, 3–15 per cent.; packing and in transit, 2–5 per cent.; boiling and washing, 5–40 per cent.; bleaching, 1.5–20 per cent.—A. L. S.

PATENTS.

Improvements in Percussion Fuses for Explosive Projectiles. A. Martin, Birmingham. Eng. Pat. 18,738, November 22, 1889. 8d.

THIS specification describes a form of fuse in which the striking pin is so held in position in a weighted plunger that it cannot act on the priming. On the gun being fired the plunger slips back over the pin, and then, when the projectile meets an obstacle, the momentum of the plunger carries the striking pin along with it by a special device, and thus the priming is fired. The fuse is fixed to the base of the projectile. Drawings illustrate the arrangements.

—W. M.

Improvements in Treating and Using Explosives whereby the Flame produced is Controlled and Quenched. A. T. Coeking, Rotherham. Eng. Pat. 19,935, December 11, 1889. 6d.

SMALL blocks of a plastic substance formed of 5 parts of water and 1 part of either starch, soap, gelatin, glue, or Irish moss, and a chemical such as oxalic acid or ammonium chloride in sufficient proportion, are placed in the bottom of the bore-hole, and on top of the cartridge; the hole is filled in the usual manner. Or the solution of fire-extinguishing chemicals may be absorbed in an envelope of wool or flannel and the cartridge placed in it, and fired while the composition is in a damp state.—W. M.

Improvements in Percussion Fuses for Explosive Projectiles. A. Martin, Birmingham. Eng. Pat. 19,971, December 11, 1889. 8d.

THIS is an improvement on Eng. Pat. 18,738 of 1889 (see above), the main feature of which is the adaptation of the fuse to the point or head of the projectile instead of the base, a passage being left through the striking pin to afford communication between the priming and the explosive charge.—W. M.

Apparatus for Cutting into Lengths and Delivering Smokeless Explosive or other Plastic Material which has been Moulded through a Die. E. W. Anderson, Erith. Eng. Pat. 20,286, December 17, 1889. 11d.

THIS apparatus, which is preferably fixed to the machine used in pressing out the explosive in the form of rods or

cord, consists of an endless belt, suitably supported, on which are attached at proper intervals, according to the length of rods required, narrow knives standing across the width of the belt. The explosive, as it issues from the die, is delivered on to this belt and carried forward. The belt passes between two rollers, or a roller and fixed block so arranged that at this point the rod or cord of explosive is cut, and passing on is removed from the belt.—W. M.

Improvements relating to Machines or Apparatus for the Manufacture of Explosives, and for similar Purposes. H. S. Maxim, Westminster. Eng. Pat. 1951, February 5, 1890. 1s. 1d.

THIS invention relates to the manufacture of explosives in grains from, for example, gun-cotton dissolved in acetone, and the object is to carry on manufacture continuously in a machine in which all the operations are effected automatically. The gun-cotton and solvent are introduced into the hopper of the machine, and then pass into a cylinder in which the ingredients are thoroughly mixed by means of knives arranged helically on a shaft; the mass is thus also pressed against the end of the cylinder remote from the hopper and through devices for forming the material into slips and cutting these into grains. Numerous drawings accompany the specification.—W. M.

Improvements in or relating to Lucifer Matches. W. P. Thompson, Liverpool. From J. Hess, Antwerp, Belgium. Eng. Pat. 1995, February 6, 1890. 4d.

THE invention consists in placing on different parts of the same match the two compositions, which, used in ordinary safety matches, are placed the one on the box, and the other on the match. To strike a light, this improved match is broken in the middle and the two ends rubbed together.

—W. M.

Improvements in the Manufacture of Explosives. J. Y. Johnson, London. From C. Pieper, Berlin, Germany. Eng. Pat. 2547, February 17, 1890. 6d.

NITROCELLULOSE alone or mixed with potassium nitrate, camphor, &c., is first gelatinised by kneading with a suitable solvent until the mass has become quite plastic. When this mass is stirred in a warm liquid or vapour which does not act chemically on it, it splits up into grains. The author preferably employs water or steam. The excess of the solvent is removed by boiling the explosive in water or other liquid, and it may be recovered by condensation.

—W. M.

Improvements in Percussion Fuses. H. A. Schlund, Birmingham. Eng. Pat. 2769, February 20, 1890. 6d.

"THE invention relates to further improvements in percussion fuses of the kind described in the specification of patent No. 112 of 1886 for use with shell torpedoes, and the like, the object of the present invention being to adapt the principle of the fuse described in the said former specification No. 112 of 1886 to fuses that are screwed from the outside into the base of shells, and also to produce more uniform results in the working of the fuse."

For particulars, the original specifications and drawings must be consulted.—W. M.

Improvements in Explosive Shells. H. P. Merriam, New York, U.S.A. Eng. Pat. 10,170, July 1, 1890. 1s. 7d.

THIS "invention relates more particularly to mechanical devices whereby the explosive material projected in the shell is detonated instantaneously or at an interval succeeding the initial concussion, according to the nature of the target. In the event of impact upon a solid target the immediate detonation of the explosive charge is provided for; whereas in event of immersion an element of delay in the action of the detonator is allowed, whereby the projectile may become submerged beneath a hostile vessel or other floating object

before exploding." For details the original specification must be consulted. There are twelve sheets of drawings and fifty-five claims.—W. M.

Improvements in Apparatus for Charging Metallic Cartridge Cases with Liquid Carbonic Acid Gas and in the Construction of such Cartridge Cases. P. Giffard, Paris, France. Eng. Pat. 10,308, July 3, 1890. 8d.

This invention has reference to Eng. Pat. 11,050 of 1889, and consists chiefly of apparatus whereby the charging of the cartridge cases with liquid carbonic acid gas can be effected in a very rapid and certain manner. The original specification must be consulted for particulars. It is illustrated by drawings.—W. M.

Improvements relating to Explosive Compounds. J. S. Walter, London. Eng. Pat. 18,519, November 17, 1890. 4d.

Picric acid is first melted and then sufficient sawdust or other absorbent added to take up all the melted acid.

This mass is then mixed with more untreated sawdust and a solution of potassium nitrate, and finally flowers of sulphur is added. After thorough mixing and drying the explosive is ready for use. It is stated that 2 oz. of "treated sawdust," prepared as above, contains about 1 oz. 4 drms. of picric acid. The following proportions are recommended:—

	Lb.	Oz.	Grms.
Treated sawdust.....	0	2	2
Untreated sawdust.....	0	14	0
Nitrate of Potash.....	3	12	0
Flowers of sulphur.....	0	10	0
	3	6	2

—W. M.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

Apparatus for Fractional Distillation under Reduced Pressure. H. Wislicenus. Ber. 23, 3292—3295.

In connexion with the apparatus it is very convenient to have an arrangement for preventing backflow of water from the pump. Such an arrangement is shown in section in Fig. 1.

Fig. 1.

Fig. 2.

"SAFETY VALVE
FOR WATER-LIFT
PUMP."

APPARATUS FOR
FRACTIONAL DISTILLATION
UNDER REDUCED PRESSURE.

It is of glass and consists of two parts A and B. The lower extended portion *e* of A is pierced in the side with a small hole *o*, covered by means of a piece of rubber tubing cut as shown. A is connected with the vessel to be exhausted, B is fastened by rubber tubing to the pump. When the pump is working A and B are sucked together and the joint is kept air-tight by means of a rubber ring *r*; the air from the vessel undergoing exhaustion escapes easily from *o*, but supposing water to suck back from the pump the connection at *r* immediately gives way, and furthermore the opening *o* is immediately closed by external pressure.

The actual apparatus for the distillation is shown in Fig. 2.

Into the neck of a bell-jar is fitted a rubber stopper, through which passes the suction tube C; fitting into C by means of a rubber ring is the glass tube B, so bent that by merely turning it round its lower end may be brought in turn over the mouths of a number of test tubes arranged in a circle in the bell-jar. Into B fits, by means of another rubber ring, the adapter A, which is attached, as shown, to the condenser of the apparatus. It is advisable to have a rubber tube pushed over the upper wide end of B, and also over A and C.—T. L. B.

A New Form of Air Thermometer for Technical Purposes.

A. H. Sabine. J. Amer. Chem. Soc. 1890, 12, 277—282.

Description.—A Bulb; B Safety chamber for air and mercury; C Cylinder filled with mercury; D Air pressure-gauge; E Capillary tube; F Piston with screw to force mercury from C; *x y* Horizontal line showing constant level of mercury in capillary tube and gauge glass.

A NEW FORM OF AIR THERMOMETER.

The bulb A is a cast-iron vessel of 160 cc. capacity, communicating by the capillary glass tube E with the cylinder B filled with mercury, the piston chamber C, and the compressed air manometer D. The vertical capillary tube is connected to the iron vessel by an asbestos-packed joint. In order to determine the temperature of a chamber, A is introduced into it, the rest of the apparatus, with the exception of the capillary tube, being at the ordinary temperature, and the mercury is brought to a fixed point on the tube E by means of the piston and the moveable air gauge D, which is connected to the rest of the system by a piece of caoutchouc tubing. The mercury in D and in B being at the same height, the pressure in A must be equal to the pressure of the air in the upper part of D, and this pressure is known from the diminution in its volume; its temperature is indicated by means of an internal thermometer. Now, since the pressure of the air is proportional to $(273 + T)$, where T is the temperature in degrees Centigrade, or to $(159 + t)$ where t is the temperature in degrees Fahrenheit, the volume being constant, we can

calculate the temperature from this pressure approximately, by assuming the volume of A to be constant, and neglecting, in the first instance, the small expansion of the iron. We get a second and nearer approximation by (1) using the first series of numbers obtained to calculate approximately the expansion of the iron vessel, and then (2) allowing for this increase of volume in the calculation of the temperature.

—P. J. II.

Determination of the Solubility of Salts. F. Rüdorff, *Zeits. f. angew. Chem.* 1890, 633—634.

In determinations of the solubility of salts the great difficulty is the filtration of the small sample at the desired temperature. This may be conveniently effected by the apparatus shown in the figure.

THE SOLUBILITY OF SALTS.

The small bottle A has a height of 4 cm. and is 2 cm. in diameter at the bottom; it is provided with a ground stopper. B is a doubly-bored cork, through one hole of which passes a narrow glass tube C, open at both ends, through the other a small tube, the upper opening of which is covered with a piece of cambric; over this passes a rubber tube D, into which fits the glass rod E.

A standard solution of the salt under examination is made in a wide test tube at a temperature which is higher than the temperature of determination; the test tube, with contents, is then placed in a beaker of warm water, kept warm on a sand-bath. The contents of the test tube cool down to the temperature of the water in the beaker, and then the apparatus above described is used for agitating the solution under examination. A little of the solution is allowed to flow into the rubber tube and so on to the cambric filter by momentarily removing the glass rod. The upper portion of the apparatus is replaced by the ground stopper, and the bottle exterior is freed from adhering solution by means of water. From the weight of the filtered solution in the bottle and the amount of salt in such solution, the solubility is easily ascertained. A series of determinations at different temperatures is very conveniently made with this apparatus.—T. L. B.

New Form of Apparatus for the Determination of Methoxyl (OCH_3). L. Ehmman. *Chem. Zeit.* 14, 1767.

This is a modification of the apparatus devised by Benedikt and Grüssner (this Journal, 1890, 735) for the determination of methoxyl, by means of which several determinations can be made at once, and in which the cooling with a current of warm water is dispensed with.

The estimation is carried on in exactly the same way as in the original form of the apparatus. The decomposition takes place in the flask F, to which the absorption bulbs B and C, which are filled with water and red phosphorus, are connected by the bent tube r. These bulbs are kept at a constant temperature in the copper water-bath f, which can be arranged to accommodate several pairs of bulbs;

they are supported by the clamp screw S, and the screws k, k, which also serve to hold the thermometer and the temperature regulator R. The tube s leading from the absorption bulbs is fitted by means of a cork into a second tube widened out at the end, as shown in the figure, and this latter dips into the silver nitrate solution; the object of this arrangement is to avoid the troublesome cleaning of the tube s.

APPARATUS FOR THE DETERMINATION OF METHOXYL.

L' is a special form of condenser to be placed above the evolution flask F in the case of specially volatile substances.

—C. A. K.

Apparatus for Gas Analysis. J. J. Morgan. *English Mechanic and World of Science*, October 31, 1890.

J. PARRY has arranged an apparatus for analysing producer and other gases. It is a modification of Hempel's apparatus

Fig. 1.

Fig. 2.

Fig. 3.

APPARATUS FOR GAS ANALYSIS.

(this Journal, 1885, 160), essentially differing from it, as will be readily understood from the accompanying diagram, in that the measuring tube for the gas is surrounded by water. Fig. 1 represents the measuring tube corresponding to Hempel's burette. Fig. 2 represents the absorption apparatus corresponding to Hempel's simple absorption pipette. Fig. 3 represents the apparatus employed in the determination of the hydrogen by explosion similar to Hempel's explosion pipette.—K. E. M.

Wood-Wool Absorption Plates. W. Camerer. Zeits. Anal. Chem. 29, 576.

PLATES for rapidly drying filters or preparations are usually made of earthenware or gypsum. The author has had plates which better serve the purpose intended, made from wood-wool. Sometimes the plates are made with a surface of cellulose which makes a smoother surface. Such plates have been in use for 1½ years, and have remained in good order. They cost from 20—40 pfennige (2½d. to 5d.) each.

—H. S. P.

INORGANIC CHEMISTRY.— QUALITATIVE.

A Simple Test for Tar Products in Ammonia. Bernbeck. Pharm. Zeit. 1890, 35, 691.

If ammonia containing tarry impurities be carefully poured on the surface of crude nitric acid, an intense eosin colour will be formed at the line of demarcation of the two liquids.

—H. T. P.

INORGANIC CHEMISTRY.— QUANTITATIVE.

Estimation of Vanadic Acid in Vanadotungstates.
A. Rosenheim. Ber. 23, 3208—3210.

ROTHENBACH has stated (Ber. 23, 3060) that the violet colouration, produced in the reduction of solutions of vanadotungstates containing phosphoric, with sulphurous acid, is not due to the reduction of the tungstic acid existing in solution as phosphotungstic acid; in proof of this statement he quotes the fact that a solution of vanadium tetroxide, from which the sulphurous acid has been completely expelled, gives a violet colouration with phosphotungstic acid, the cause of which is, he says, according to the author, a partial reduction of the tungstic acid.

The author denies having stated that sulphurous acid reduces tungstic acid, and proceeds to show that the violet colouration produced in the case quoted by Rothenbach is due to the reduction of the tungstic acid by the vanadium tetroxide.

When equal volumes of solutions of phosphotungstic acid of different concentration are treated with equal quantities of a vanadyl solution, a violet colouration is produced in the cold, and the colour, which varies from that of concentrated potassium permanganate to a dull violet grey, is the more intense the larger the quantity of tungstic acid present. When, on the other hand, vanadyl solutions of different concentration are mixed with equal quantities of a solution of phosphotungstic acid, there is no difference in the intensities of the colourations produced.

This reaction between tungstic acid and vanadium tetroxide is without influence on the results when vanadic acid is titrated with potassium permanganate in presence of tungstic acid, because the oxidation of the vanadyl compound is compensated by the reduction of the tungstic acid; the end of the reaction is, however, so difficult to observe owing to the violet colour, that, as Friedheim has shown, the results obtained by different observers may differ by as much as 4 per cent. Friedheim's direct method (Ber. 23, 353) for the separation of tungstic acid and vanadic acid is, therefore, to be preferred to Gibbs' and the author's indirect process.—F. S. K.

Determination of Nitrogen in Nitrates. A. Süllwald. Chem. Zeit. 14, 1673.

THE author compares Jodlbauer's method with Foerster's method, and concludes that while equally accurate the latter being the simpler of the two is decidedly preferable. Foerster's method consists in dissolving 0.5 gm. of saltpetre in 15 cc. of sulphuric acid containing 6 per cent. of salicylic acid. 5 grms. of sodium thiosulphate are now added, and after the completion of the reaction, mercury and 10 cc. pure sulphuric acid. The following modification of Jodlbauer's method is also described. 0.5 gm. of saltpetre or 1 gm. of the nitrate mixture are moistened with 0.5 cc. of water. 25 cc. of a mixture containing 20 grms. of phenol to 500 grms. of sulphuric acid are now slowly added, and when all is dissolved, 2.5 grms. of zinc powder. After 15 minutes, mercury is added and the mixture heated. To prevent loss of ammonia during distillation the tube of the condenser is allowed to dip under sulphuric acid.—A. R.

Determination of Nitrogen in Nitrates. A. Süllwald. Chem. Zeit. 14, 1748.

FOERSTER'S method of determining nitrogen in Chili saltpetre has the disadvantage that the latter substance does not readily dissolve in the mixture of salicylic and sulphuric acids. The author prefers to use a modification of Jodlbauer's method (see previous abstract).—A. R.

The Use of the Gooch Crucible as a Silver Voltmeter.
M. Loeb. J. Amer. Chem. Soc. 1890, 12, 300—301.

IN order to avoid loss of silver by the washing of the deposit in a voltmeter, the author uses a modification of the Gooch crucible. A rather tall and narrow platinum crucible perforated at the bottom is fitted into a glass cup terminating in a syphon. The two are united by a piece of rubber tubing which should be freed from sulphur, although there is no real danger of contact with the silver solution. The apparatus is filled with silver nitrate solution, so that the top of the syphon is not quite reached, and is then set upon the stand. The crucible rests in a well-fitting brass block to which the negative wire is attached. The anode consists of a silver cone suspended within the crucible by means of a silver wire attached to a horizontal bar insulated from the cast-iron base.

When the electrolysis is complete, the residual nitrate of silver can be entirely removed, without in any way disturbing the deposit, by filling up the crucible with hot water several times. The crucible is then detached from the syphon, dried and weighed.—P. J. H.

ORGANIC CHEMISTRY.—QUALITATIVE.

Note on Schiff's Reaction. O. F. Müller. Zeits. f. angew. Chem. 1890, 634—636.

SOME red lakes made from magenta turn violet; the author has, therefore, been led to study the action of certain resins and their solvents on magenta solution decolourised by sulphur dioxide. Different kinds of shellac, gum damar, gum benzoin, and various kinds of turpentine gave violet to reddish-violet colourations. Methyl alcohol gives a violet colouration, gradually increasing in intensity for some time; on quickly boiling the violet is changed to magenta, which on standing again becomes violet; excess of sulphur dioxide decolourises the solution. Ethyl alcohol gives a reddish violet colouration; on quickly boiling it becomes of a magenta colour, and on cooling only slight change takes place; excess of sulphur dioxide bleaches the solution. Amyl alcohol gives only a faint reddish violet. Glycerin gives no reaction. Aldehyde shows a reddish violet, turning darker violet with a blue shade. Acetone produces slowly a reddish violet. Oleic acid and kaulin give violet colourations; gum arabic no colouration whatever.

Excess of sulphur dioxide has no effect on the resin lakes, neither are these affected by heat. On addition of dilute

acids to a solution or emulsion of the resins in borax solution, first the resin lake is precipitated, then the excess of resin. On addition of hydrochloric acid the violet colouration turns to blue and green, and finally the whole becomes colourless; neutralisation with ammonia brings back the original colouration.

Methyl violet R and B give similar reactions to magenta.

Ethyl violet gives no reaction with methyl and ethyl alcohol, and only a faint reaction with aldehyde and acetone.

—T. L. B.

Detection of Vegetable-wax in Beeswax. H. Röttger. Chem. Zeit. **14**, 1473—1474. (See this Journal, 1890, 83 and 771.)

The author considers that Hager's method for the detection of Japan wax in beeswax by means of the specific gravity unreliable. Hager's second method is to dissolve 0.5 gm. of borax in a test tube in 6—8 cc. of water, 0.3—0.4 gm. of the wax are then added, the mixture boiled and allowed to stand, when the wax, if pure, solidifies and floats above the clear liquid. In presence of impurities the whole remains turbid and thick, (Chem. Zeit. **14**, 606). The results of experiments made with this method by the author is that with pure wax an emulsion is always formed between the wax and clear borax solution, and that in the presence of Japan wax, stearic acid and resin the test is not very reliable because the separation of the whole into layers, after heating, lacks sharpness. With 5 per cent. of either stearic acid or resin no solid layer separates and the whole forms a thick emulsion. For the detection of small quantities of Japan wax or of tallow, the method is untrustworthy; in presence of 10 per cent. of the former the whole of the liquid below the crust of solid wax appears as a thick emulsion, which only begins to clear after a few days.

The method recommended by a Commission of the German Society of Apothecaries (Arch. Pharm. **24**, 490) is to boil 1 gm. of the wax with 10 cc. of water and 3 grms. of sodium carbonate for a quarter of an hour and allow to cool, when the wax separates as a crust and the underlying solution remains only slightly cloudy in the case of pure wax. But in presence of impurities an emulsion is formed beneath the crust of wax. The results of the author's experiments by this method show that 2 per cent. of Japan wax, stearic acid or resin can be recognised in beeswax by the abnormal character of the emulsion formed, whilst in the case of an admixture of tallow the test is less delicate, only 5 per cent. being recognisable.—C. A. K.

Examination of Glycerin according to the New German Pharmacopœia. B. Jaffé. Chem. Zeit. **14**, 1493.

THE new Pharmacopœia describes a method of testing glycerin by means of ammoniacal silver solution. This has given rise to considerable discussion, both as to its value and the way in which the test is to be carried out.

Glycerins which have been merely decolourised, and not distilled, stand the test, and such glycerins contain almost all the impurities of crude glycerin. Furthermore, refined glycerin with several per cent. of arsenious acid subsequently added likewise stood the test. Only such products may be detected, therefore, as are produced by the distillation of glycerin, viz., formic acid, acrolein. And yet even several per cent. of formic acid may be present without any reduction of silver solution being shown in presence of excess of ammonia. Small quantities of acrolein may be detected by the smell, and yet it cannot be assumed that odourless glycerins contain merely negligible quantities of acrolein. With regard to the manner of carrying out the test the author asserts his absolute inability to obtain constant results.—T. L. B.

Food Examination. J. Pinette. Chem. Zeit. **14**, 1570—1571.

Detection of Salicylic Acid in Beer.—To 50 cc. of beer in a separating funnel are added 5 cc. of alcohol (to promote separation of the extracting liquid), 5 cc. of sulphuric acid (1 in 10) and 50 cc. of a mixture of equal volumes of ether and petroleum spirit, and the whole is thoroughly shaken. The ethereal extract is distilled to a small bulk, and the residue is shaken up with a few centimetres of water and a few drops of a weak ferric chloride solution. In presence of salicylic acid, the aqueous layer assumes a splendid violet colouration.

Butter may be rapidly analysed as follows:—A small weighing bottle containing a glass rod has about 5 grms. of butter weighed into it. About 2 grms. of it are transferred to a separator of 230 cc. capacity and graduated up to 200 cc. The remainder of the butter in the weighing-bottle is dried at 100° C.; loss of weight represents water. In order to facilitate the expulsion of the moisture, small quantities of alcohol are occasionally added, and the butter is well stirred.

100 cc. of a mixture of equal volumes of ether and petroleum spirit are placed in the separator and shaken about until the butter is dissolved. Then add 20 cc. of alcohol and sufficient water to make the liquid nearly up to the top graduation. The stopper is next inserted and tied down with string, and the separator is thoroughly shaken until on resting for a moment the top layer begins to separate clear. The mixture is then allowed to stand for some time and the volume of the different layers is noted. An aliquot portion of the ethereal layer is evaporated to dryness, and the residue, consisting of butter fat, is weighed. A portion of the aqueous layer is titrated for chlorine with silver nitrate, using potassium chromate as an indicator, the chlorine found being calculated into salt. The ash, other than salt, is always assumed to be 0.2 per cent. Then, 100, less the sum of fat, water, salt, and 0.2 represents organic matter, not fat. If the butter be rancid, the acidity may be estimated by dissolving the residue from the determination of butter fat in a mixture of alcohol and ether (1:2), adding some phenolphthalein, and titrating the solution with decinormal sodium hydrate.—H. T. P.

Pyrrrol, a Reagent for Aldehydes. Lepidine, $C_{10}H_9N$, a Reagent for Wood, and for a Series of Etheral Oils. A. Ihl. Chem. Zeit. **14**, 1571.

An alcoholic solution of pyrrrol is, in presence of hydrochloric acid, the most delicate of all the known tests for lignin; in fact, it is a test for all aldehydes.

Wood, moistened with an alcoholic solution of lepidine, and then with hydrochloric acid, is stained a bright red. Etheral oils containing a derivative of allyl benzene give similar reactions. Oil of cinnamon, treated with an alcoholic solution of lepidine and with hydrochloric acid, gives a splendid bright red colour. The oils of pimento and cloves yield a yellow precipitate, which rapidly turns intensely red. Sassafras oil also forms a yellowish precipitate, turning red. Esdragon oil yields a white precipitate, which quickly changes to a bright vermilion hue. Fennel and anise seed oils only give a yellowish colouration. Pyrrrol gives similar reactions to the above, but is considerably more sensitive than lepidine. (See also this Journal, 1887, 306; 1888, 51; 1889, 421, 640, 914, and 1012; 1890, 418, 555, and 770.)—H. T. P.

A New Reagent for Vanilline. Thiophen, a Reagent for the Substances forming the Incrustation of Wood. A. Ihl. Chem. Zeit. **14**, 1707.

ALCOHOLIC solutions of vanilline mixed with a little thiophen and concentrated sulphuric acid are coloured green to bluish-green.

The author has likewise found that when wood is moistened with a mixture of 1—2 drops of thiophen and about 10 times the quantity of alcohol mixed with an equal volume of sulphuric acid added, the wood is gradually coloured green.—A. R.

A Test for Resorcinol and for Thymol. H. Borntrager. *Zeits. Anal. Chem.* **29**, 572—573.

Resorcinol and thymol both give a red colour when warmed with nitrous acid, the former giving a blood red colour and the latter a yellow-red. The coloured solution is clear in the case of resorcinol, both in aqueous and alcoholic solutions, but in the case of thymol the alcoholic solution is clear, whilst the aqueous solution yields a flocculent yellow red precipitate. In the case of thymol also the extremely characteristic fruity odour of thymol nitrite is observed. To further distinguish them, a mixture in about equal proportions of a salt of nitrous acid, gypsum, and sodium bisulphate is put into a test tube, moistened with water, and the liquid to be tested is then added, and the whole warmed. If thymol be present, the mixture becomes chrome-red, if resorcinol be present it turns a dark chrome-green colour, and magenta-red drops collect on the upper part of the test tube.—H. S. P.

ORGANIC CHEMISTRY.—QUANTITATIVE.

On the Indices of Refraction of Fatty, Mineral, and Resin Oils. Hölde. *Mitt. Königl. tech. Versuchs.* 1890, 269—270.

The indices of refraction are stated to be of analytical value for the determination of different oils (see Amagat's and Jean's experiments in Schaeffler's *Untersuch. d. Fette u. Öle*, 1890, 78). The following average results which the author obtained with Abbe's refractometer, seem to confirm this. The temperature of the testing room was always about 20° C.

	Refined Rape Oil.	Crude Rape Oil.	Olive Oil.	Mineral Oil.	Resin Oil.
Limits of indices of refraction.	1.4722 and 1.4735	1.4735 and 1.4750	1.4670 and 1.4705	1.4776 and 1.4980	1.5274 and 1.5445
Mean index of refraction	1.4728	1.4744	1.4688	1.4923	1.5344

It is hoped that this test may be useful, especially for detecting the presence of rape oil in olive oil to which it is frequently added as adulteration.—H. S.

On the Methods in use for the Quantitative Estimation of Acetone. F. Collschon. *Zeits. Anal. Chem.* **29**, 562—572.

PRACTICALLY the only two methods in use are Kramer's gravimetric method (*Ber.* **13**, 1000) and Messinger's volumetric method (*Ber.* **21**, 3366; this *Journal*, 1889, 138). Kramer's method has been repeatedly investigated and the sources of error pointed out by various chemists, among others by Hutz (*Zeits. Anal. Chem.* **27**, 182; this *Journal*, 1888, 459), and more recently by Vignon (*Compt. Rend.* **110**, 534; this *Journal*, 1890, 659).

The author recommends Messinger's volumetric method in preference to Kramer's, and finds it for all practical purposes quite as reliable and more simple, and an estimation can be made in five minutes by it, whilst Kramer's process requires from one to two hours. In spite of these advantages the author thinks that the volumetric method has not met with general adoption, and probably because the results obtained have not been consistent. The degree of dilution of the acetone solution is generally supposed to have an important bearing upon the result, but he has not found this to be the case. He obtains the same results when the acetone is diluted in the ratio 1.10 up to 1.500. Dilution merely retards the reaction. He recommends, however, that a $\frac{1}{2}$ or 1 per cent. solution be used. With a high percentage acetone

it is only necessary to dilute 10 cc. to 1 litre, and take 5—10 cc. of this for analysis. In measuring the solutions the temperature must be observed, owing to the considerable change in the specific gravity of acetone caused by changes of temperature. Messinger's method is applicable to commercial acetones, to methylated spirit, methyl alcohol, crude acetones, and to testing unfinished products during manufacture. It depends (as well as Kramer's method) upon the reactions expressed in the equation—

When an excess of iodine solution is added to a solution of acetone mixed with a solution of potassium hydrate, 6 atoms of iodine react with 1 molecule of acetone and form 1 molecule of iodoform, and the iodine in excess forms potassium iodide and potassium hypoiodite, which splits up into potassium iodide and potassium iodate. On acidulating the solution the two latter compounds are decomposed, and iodine is liberated, which can then be titrated. The original quantity of iodine added being known the amount that has been combined to form iodoform is easily calculated, and from this the percentage of acetone present in the solution determined. Messinger describes his mode of procedure as follows:—From 20 to 30 cc. of a solution of potassium hydrate (56 grms. KOH in 1 litre H_2O) are introduced into a 250 cc. flask which has a well-fitting ground stopper, 1—2 cc. of methyl alcohol (or a suitable quantity of diluted acetone) added, and the mixture well shaken. A measured volume of one-fifth normal solution of iodine is added and shaken up for $\frac{1}{4}$ — $\frac{1}{2}$ minute, until the solution becomes clear. The mixture is then acidulated with hydrochloric acid (1.025 sp. gr.) an excess of decinormal sodium thiosulphate solution added, and the excess determined by titration with iodine solution using starch as indicator. The caustic alkali should be free from nitrite, or the quantity of this determined.

The author finds that sodium hydrate and sulphuric acid may be substituted for potassium hydrate and hydrochloric acid. He also lays stress on the two following points: 1. If, after the addition of the iodine solution the reaction, owing to lowness of temperature, be not completed in the time mentioned by Messinger, viz., $\frac{1}{4}$ — $\frac{1}{2}$ minute, the mixture must be energetically shaken for four or five minutes, or, instead of shaking so long, the reaction may be accelerated by shaking the flask for two minutes in water at 60°—70° C., but the temperature must not be raised above 70°. At 80° some iodate begins to be reduced, and in testing methyl alcohol, or when this body is present, the solution, to avoid reduction of iodate, should on no account be warmed. 2. The mixture of acetone and caustic alkali must be continuously shaken during the addition of the iodine solution, and the latter must be added slowly and in sufficient excess. The author finds that an excess of one quarter of the theoretical amount is sufficient. He shows by experiment that the splitting up of the potassium hypoiodite into iodate and iodide takes place very rapidly, and that in a mixture of 20 cc. of one-fifth normal iodine solution, and 30 cc. sodium hydrate solution, after two minutes, about 75 per cent. of the hypoiodite will have split up into iodate and iodide:—

On this account it is necessary, in order to avoid the need of adding a large excess of iodine, to shake the mixture vigorously during the addition of the iodine, so as to bring the acetone at once in contact with the hypoiodite formed, and so that the reaction may follow the line expressed by the equation—

It is not possible to do this completely, and for this reason it is necessary to add at least seven atoms of iodine instead of six to each molecule of acetone. If the precaution of thoroughly mixing is not observed, the proportion of iodine must be increased. The author points out that the method cannot give absolutely correct results, because it

does not actually determine acetone alone, but at the same time all other substances present that are capable of forming iodoform. We have as yet no method by which to determine the acetone alone.—H. S. P.

The Examination of Brewers' Pitch. Z. v. Milkowski
Zeits. Anal. Chem. **29**, 573—576.

FROM 0.5 gm. to 1 gm. of the pitch is saponified with alcoholic potash, the solution evaporated to dryness, and the residue taken up with water. The dissolved soap is then treated with ether, either in a separating funnel or in the extracting apparatus shown in Fig. 1. The part soluble in ether is the "neutral resin"; it is dried and weighed on a weighed watch-glass. The soap is then treated with dilute hydrochloric acid either in the separating funnel or in the extracting apparatus. Resin and fatty acids separate out in a flocculent precipitate, and are dissolved out or extracted with ether and well washed with water. The ethereal solution is then evaporated to dryness and the residue dried at 100° and weighed. The residue is then dissolved in from 15 to 20 cc. of alcohol, potassium hydrate solution added until the solution is alkaline, evaporated to a volume of 5 cc., taken up with water and the resin and fatty acids precipitated with a silver salt. The precipitate is filtered off, dried at 100°, and extracted with ether in Soxhlet's apparatus; or the aqueous solution may be precipitated in the flask B of the extracting apparatus, Fig. 1, and extracted directly with ether. The resin and

FIG. 1.

FIG. 2.

THE EXAMINATION OF BREWERS' PITCH.

traces of silver go into solution. In the first mode of working, the silver is precipitated by hydrochloric acid and filtered, and the ethereal solution of the resin collected in a dried glass, the ether evaporated, and the residue of resin dried and weighed. When the extracting apparatus is used, a flask containing dilute hydrochloric acid and a flask containing water are inserted. The ethereal solution of resin is thus obtained free from silver and from acid, and is dried at 100° and weighed. The silver salts of the fatty acids are then decomposed with hydrochloric acid, the liberated acids taken up with ether, dried, and weighed. The kind of fat may be determined by aid of the saponification numbers. These methods may be carried out by using separating funnels, but the apparatus shown in Fig. 2 is much more convenient and more exact. The apparatus is a modification of that of Schwarz (Zeits. Anal. Chem. **23**, 368; this Journal, 1884, 648). The flask A holds the extracting liquid; flask B, the solution to be extracted; C and D are washing flasks, C containing diluted hydrochloric acid and D distilled water.

Below are the average results obtained from several analyses of pitch using separating funnels in one set of determinations and the extracting apparatus in another:—

	Separating Funnel.	Extracting Apparatus.
Natural resin	Per Cent. 11.23	Per Cent. 11.52
Resin	74.28	74.86
Fatty oil	13.05	13.42

—H. S. P.

The Analysis of Crude Tartar and Wine Lees.
B. Phillips and Co. Zeits. Anal. Chem. **29**, 577—579.

To estimate the acid potassium tartrate in tartar and wine lees, the authors recommend the following method as being simple and sufficiently accurate. 10 grms. of the tartar or yeast are boiled with 150 cc. of water, and the solution neutralised exactly with sodium or potassium hydrate. All the potassium bitartrate goes into solution, leaving the calcium tartrate undissolved. The whole is then afterwards treated according to the improved process of Goldenberg, Geromont, and Co., that is to say, the whole of the solution together with the insoluble lime salt is put into a 200 cc. flask, the flask filled to the mark (in the case of lees, to 203 cc.), and from 100 cc. of this solution the potassium bitartrate is precipitated. Since the solution contains no potassium carbonate, only 3 cc. of glacial acetic acid are added instead of 5 cc., as in Goldenberg and Co.'s method. The result obtained by this method gives the amount of acid potassium tartrate, whilst the difference between this amount and the total tartaric acid found by Goldenberg, Geromont, and Co.'s method, gives the quantity of calcium tartrate in its equivalent of acid potassium tartrate.

Note by R. Fresenius.

The improved method of Goldenberg, Geromont, and Co. is founded upon the work of F. Gantter (Zeits. Anal. Chem. **26**, 714) and N. v. Lorenz (Zeits. Anal. Chem. **27**, 8; this Journal, 1888, 136), and upon many experiments in Fresenius' laboratory bearing upon the original method of Goldenberg, Geromont, and Co. (Zeits. Anal. Chem. **22**, 270). 10 grms. of tartar or yeast are boiled with 150 cc. water and 7 grms. potassium carbonate for 30 minutes, during which time the solution is repeatedly stirred. The whole is then transferred to a 200 cc. flask and made up to this volume, or to 203 cc. in the case of the yeast, to allow for the volume of water displaced by the undissolved residue. The solution is then filtered on a dry filter and 100 cc. evaporated down to a volume of about 25 cc. in a dish; 5 cc. of glacial acetic acid are then added and the covered dish is warmed on the water-bath for 15 minutes. After cooling, 100 cc. of absolute alcohol are added, the solution well stirred and the precipitate, after the lapse of about 15 minutes, filtered off on a filter of 10 cm. diameter, using the filter pump. The precipitate is then washed with 96 per cent. alcohol until 20 cc. of the washings diluted with an equal volume of water show an alkaline reaction on the addition of three drops of one-fifth normal caustic potash solution. The filter and precipitate are then returned to the dish, about 200 cc. of water added, boiled, and titrated with semi-normal caustic solution, using sensitive neutral litmus paper as indicator. When the solution just shows a feebly acid reaction, it is again boiled a short time and then rapidly titrated to a finish. The caustic solution must be standardised with chemically pure tartaric acid, dried at 100°, using the same kind of litmus paper as indicator.—H. S. P.

Sugar Estimation with Fehling's Solution. BAUMANN. Zeits. f. Zuckerind. 1890, 40, 778.

SOME of the best filter papers allow considerable quantities of cuprous oxide to run through, even when no pump is used; absorption of copper also takes place. It would seem, therefore, safer to return to the asbestos filter. The recognised tables used with the sugar method have with certain abnormal products given somewhat unexpected results, and the copper obtained by three minutes' boiling was lower by 1—2 mgrms. than that obtained by two minutes' boiling. Repetition proves the results after three minutes to be correct. The recalculated tables are as follows:—

Copper.	Cane Sugar.	Copper.	Cane Sugar.
Mgrms.	Mgrms.	Mgrms.	Mgrms.
80	10.5	180	21.0
90	15.4	190	26.2
100	20.3	200	31.4
110	25.3	210	36.7
120	30.2	220	42.2
130	35.3	230	47.5
140	40.4	240	52.9
150	45.5	250	58.4
160	50.6	260	63.9
170	55.7

A Contribution to the Prevention of Coal-dust Explosions. MEISSNER. Zeits. f. Berg-, Hütten-, und Salinenw. 1890, 38, 358.

THE best method for destroying the dangerous qualities of coal-dust in mines is by moistening it and then removing it as soon as possible. In cases where the dust occurs in the strata, having been formed by the pressure of the earth or other causes, one or more bore-holes may be made into the coal and water forced into these under considerable pressure for some hours. The result is said to be satisfactory.

—A. L. S.

New Books.

CHEMISCH-TECHNISCHES REPERTORIUM. Uebersichtlich geordnete Mittheilungen der neuesten Erfindungen, Fortschritte und Verbesserungen auf dem Gebiete der technischen und industriellen Chemie mit Hinweis auf Maschinen, Apparate und Laboratur. Herausgegeben von DR. EMIL JACOBSEN. 1889. Zweites Halbjahr: Zweite Hälfte (Schluss des Jahrganges). Berlin: R. Gaertner's Verlagsbuchhandlung. Hermann Heyfelder, Schönebergerstrasse, 26, S.W. London: H. Grevel and Co., 33, King Street, Covent Garden.

THIS part of Jacobsen's Repertorium of Chemical Technology contains all the literature, patented improvements, &c., of note occurring during the second half year of 1889 in connexion with the following branches:—Food-stuffs; Paper; Photography, &c.; Waste Residues, Deposits, Manures; Disinfection and Sanitation. Soap; Explosives; Matches; Preparation and Purification of Chemicals;

Chemical Analysis; Apparatus, Machinery, Electro-technology, Technology of Heat; Appendix. Adulteration of Trade Products, &c. The Annual Report concludes with Reviews of New Books, and the Alphabetical Index.

SEHRBUCH DER ORGANISCHEN CHEMIE, VON VICTOR MEYER und PAUL JACOBSON. In Zwei Bänden. Erster Band, Erste Hälfte. Mit zahlreichen Holzstichen im Text. Leipzig: Verlag von Veit and Comp. London: H. Grevel and Co., 33, King Street, Covent Garden. 1891.

THIS, the first half of the first volume, has now appeared. It takes the form of a somewhat large 8vo. volume, price 7s. 6d. In this part are comprised the following:—The Introduction. Chap. I. Determination of the Empirical Composition of Organic Compounds. Chap. II. Determination of the Rational Composition of Organic Compounds. Chap. III. Principles permitting of a Classification of Organic Compounds. Chap. IV. The Commonest Operations which serve for the Preparation and Investigation of Organic Compounds. (This chapter is profusely illustrated with figures representing all the necessary forms of apparatus.)

Now follows a SPECIAL PART: First Book. Compounds of the Fatty Series. Chap. I. The Paraffins. II. The Monovalent Alcohols. III. Alkyl Compounds, of which the Alkyl Group is combined with a Halogen atom or with Oxygen. IV. Alkyl Compounds, the Alkyl Group of which is combined with Sulphur (Selenium or Tellurium). V. Alkyl Compounds, the Alkyl Residue of which is united to Nitrogen. VI. Compounds of Alkyl Groups with the remaining Metalloids. VII. Compounds of Alkyl Groups with the Metals. VIII. Conversion into Carbonic Acids, Aldehydes and Ketones. The Alkyl Cyanides or Nitriles of the Fatty Acids. IX. Saturated Monobasic Carbonic Acids or Fatty Acids.

THE MINES OF HUELVA.

The United States Consular Agent at Huelva, in a report upon the mines in that province, says:—

The great copper zone which traverses the province of Huelva extends from Castilla de las Guardas, 40 kilometres west-north-west of Seville, to Ajústel, in Portugal, a distance of more than 200 kilometres, with an average width of 25 kilometres.

In this zone, among others less important, are found the mines of Río Tinto, Tharsis, La Zarza, Sotiel-Coronada, Lagunza, Peña de Hierro, La Joya, Poderosa, &c., all having great analogy in their ores, which are found in great masses and at little distance from the surface, at which point they generally terminate in immense crests of oxide of iron.

The amount of copper in these ores is very variable, but the great proportion may be taken at 2 to 3 per cent., a poverty of metal which is only compensated by the abundance of ore and the method of extraction and treatment.

This great metalliferous zone, which occupies about 2,000 square kilometres, is tapped to the port of Huelva by three lines of railway—the Río Tinto railway, the Tharsis, and the BINTRON to San Juan del Puerto. The two last are also open to public service. In the more westerly part of the province another railway, elevated for half its length, carries ore to the River Guadiana.

The general characteristics of the ore are:—Sulphur, 50 to 51 per cent.; iron, 40 to 41 per cent.; silicate, 4 to 5 per cent.; copper, 1 to 3 per cent., with variable insignificant quantities of gold, arsenic, silver, antimony, and other metals. The so-called rich ore, with 2 to 3 per cent. of copper, is exported, and the poor, of about 12 per cent., is treated by open air calcination. The amount shipped is about 700,000 tons yearly.

The mines of this province were worked by the Phenicians and the Romans, neglected by the Moors, and nearly so by the Spaniards until the middle of the last century, when the attention of the Government was seriously directed towards them. But the immense deposits only began to yield a fair part of their treasures when, 25 years ago, foreign companies bought up the great mines and began to develop them. In 1866—67 the number of steamers which loaded ore in this port was 38, with 11,514 tons, while in 1889—90 the number was 727, with 520,494 tons. In 1866 the Custom house collected 315,000 pesetas, and in 1886 about 4,000,000 pesetas.

The capital invested by the different mining companies is 251,560,288 pesetas. They pay in taxes to the public treasury 1,749,621 pesetas annually; in wages, 20,763,125 pesetas; and buy stores in this country for about 8,250,000 pesetas yearly. The number of men employed is from 17,000 to 18,000.

Besides the copper mines, there are a great many small workings of manganese, of which about 8,000 tons were shipped in 1889—90. The principal mines are near Valverde del Camino. Near Aracena ore containing antimony and silver is worked to a small extent and sent down to Seville.

There is gold in the quartz rocks and streams, but it has not been found in any workable quantity.—*Ibid.*

SALT IN GERMANY.

The latest monthly statistical report of the German Empire publishes, under the title "Salt in the German Customs District," information in regard to the production and consumption, the taxation, importation and exportation for the fiscal year 1889—90 and for the ten years from 1880—81 to 1889—90. In the last mentioned year there were in operation 14 salt-producing mines, 61 salt-works producing evaporated salt, and 14 factories producing salt as a secondary product. Of rock-salt of all kinds 500,090 tons were produced, much more than in the preceding years (in 1888—89, only 388,529 tons; in 1887—88, 386,329 tons). On the other hand, the production of evaporated salt (486,281 tons) was materially less than in the preceding year (510,902 tons). With the beginning of the fiscal year 1889—90, in consequence of a trust formed by proprietors of salt-works, the wholesale prices of evaporated salt rose considerably.

The importation of salt (chiefly English evaporated salt) into the German Customs territory amounted to 26,825 tons (28,057 tons in the preceding year and 26,112 tons in 1887—88), and was small as compared with the export from the German Customs territory, which in the past year amounted to 192,258 tons (134,171 tons in 1888—89 and 125,748 tons in 1887—88).

Of domestic and foreign salt together, 364,667 tons (1888—89, 371,869 tons; 1887—88, 360,341 tons) were placed upon the open market after payment of tax for use as table salt, which was 7.5 kilogrammes per head of population; 432,216 tons paid no tax, as being intended for cattle and for industrial purposes (1888—89, 390,812 tons; 1887—88, 388,085 tons), or 8.8 kilogrammes per head of population. The use of salt for industrial purposes increased materially as compared with the preceding year, especially in soda and Glauber's salts factories (251,450 tons, as compared with 207,417 tons in 1888—89 and 220,810 tons in 1887—88), in chemical and colour works (29,796 tons, as compared with 21,291 tons in 1888—89 and 21,100 tons in 1887—88), in the leather industry (16,705 tons, as compared with 14,335 tons in 1888—89 and 12,232 tons in 1887—88), and in the metal ware industry (15,119 tons, as compared with 10,438 tons in 1888—89 and 8,825 tons in 1887—88). On the other hand, the use of salt for feeding cattle decreased (100,727 tons, as compared with 119,440 tons in 1888—89 and 108,498 tons in 1887—88), which was due to the good quality of the cattle food harvested in 1889.—*U.S. Consular Reports, December 1890.*

NEW PROCESS OF FIRING PORCELAIN.

The large porcelain factories at Limoges have been for a long time studying the question of reducing the price of fuel. At a late congress of the manufacturers it was said that some new and cheap way of manufacturing porcelain must be found for France, or the industry which has become so famous and which employs so many of the inhabitants would be driven from French soil because of the cost of firing. It was there ascertained that the cost of firing china in Bohemia was not more than 10 francs per ton; in England it was only 13 francs per ton; for the same thing in France, at Limoges, the cost was 34.50 francs. This is an immense difference, making it impossible for the French manufacturers to make their china as cheaply as their foreign neighbours. Various devices have been tried, but with little

success. In order to compete, wages have been reduced to the lowest minimum, and still the manufacturers have in many cases lost money. The coal that is employed is necessarily costly, as a smokeless, long-flame variety is required. Many of the factories burn wood only, as that produces a purer white than the very best kinds of coal; but wood is dearer than coal. It is consequently only used in firing the muffles and in the finest grades of porcelain. A few years ago a new process was tried that baked the porcelain in a short time, but the cost made the process impracticable.

It was under such circumstances as these that one of the most progressive houses in Limoges was induced to employ petroleum or residuum oils as a fuel. To accomplish this an American firm using the Wright burner was requested to come and make a trial with the fuel. There was very much doubt and fear connected with the experiment; but after a while it was attempted, and the results were far better than anticipated. The heat was shown to be absolutely pure. No gases or smoke in any way discoloured the china, which came from the kiln much whiter and in better condition than when it is fired with the best of wood. In the muffles there was a most decided advantage. The delicate colours, which show at once the presence of the slightest quantity of gas, were perfect.

This new discovery promises to revolutionise the whole porcelain industry. It is estimated that by employing these oils there will be a reduction of about 15 or 20 per cent. in the making of china. The only question now is the present classification of residuum oils, as the present duty on petroleum (120 francs per ton) is prohibitive; but strong pressures are being brought to bear on the Government now to have fuel oils classified as fuel, which pays only 1.30 francs per ton. New hope is given to an industry that was greatly threatened, and it is very probable that the French porcelain, which all have admired so much in the past, will be brought to a greater state of perfection by this new and American invention.—*Ibid.*

MISCELLANEOUS TRADE NOTICES.

CONSUMPTION OF DISTILLED SPIRITS IN THE ARTS, MANUFACTURES, AND MEDICINE IN THE UNITED STATES.

A report on the quantity of distilled spirits consumed in the arts, manufactures, and medicine in the United States during the year ended December 31st, 1889, prepared by Mr. Henry Bower and Mr. Henry Pemberton, jun., special agents, under the direction of Mr. Frank R. Williams, expert special agent in charge of manufactures under the American census, has just been issued by Mr. Robert P. Porter, Superintendent of Census. The following information is taken from this report:—

A number of estimates have been made by various persons as to the quantity of distilled spirits consumed annually in the arts, manufactures, and medicine. These estimates have been founded upon two bases: First, the quantity of alcohol only consumed in the arts, manufactures, and medicine in the United States; and second, the quantity of distilled spirits of all kinds so consumed.

It is necessary at the outset clearly to understand this distinction in considering the work which has been done in this direction in the past.

Concerning the amount of alcohol alone so consumed, Mr. Windom, Secretary of the Treasury, in his annual report of December 4th, 1889, estimated the amount at about 6,000,000 proof gallons.

Mr. F. Miller, Commissioner of Internal Revenue, estimated, on December 6th, 1887, that 5,900,000 proof gallons of alcohol are consumed in this manner.

Mr. Green B. Baum, Commissioner of Internal Revenue, included in his report for the fiscal year ending June 30th, 1882, a statement of the quantity of alcohol only used in

the arts and manufactures, prepared from statements of collectors of the Internal Revenue Department. According to this investigation 4,269,978 proof gallons of alcohol were so used in the United States during the year ending April 1st, 1882.

From the foregoing it will appear that the estimate respecting the quantity of alcohol so consumed ranges from about 4,000,000 to 6,000,000 proof gallons.

The head of a firm in New York city dealing in alcohol, writing to the chief of the Bureau of Statistics, March 1st, 1887, estimates that less than 6,000,000 proof gallons of distilled spirits are used annually in the arts, manufactures, and medicines.

A manufacturer of chemicals in Brooklyn in 1887 estimated the quantity of spirits so consumed at 14,000,000 proof gallons.

As the total quantity of distilled spirits consumed in the United States in 1888 was 75,845,352 proof gallons, the estimate of 15 to 20 per cent., reduced to ordinary gallons, represents a consumption for the arts and manufactures of from 11,000,000 to 15,000,000 proof gallons.

As a conclusion from the foregoing, it is noted that the estimated quantity of alcohol consumed in the arts varies from 4,000,000 to 6,000,000 proof gallons, and of distilled spirits of all kinds from less than 6,000,000 to 15,000,000 proof gallons.—*Board of Trade Journal*.

FURTHER TIN DISCOVERIES IN TEXAS.

The *St. Louis Age of Steel* says that:—

"Specimens of the new tin discoveries recently made in Texas have been received at San Antonio. The ores were taken there to be sampled. The mineral has been found in workable quantities on the Colorado River, in Llano county, 100 miles north-west of San Antonio, south of the Ballinger iron hill. The specimens are cassiterite, and the deposit covers a large extent. It lays near the iron fields, and was passed by unrecognised by the miners. Professor Comstock, Assistant State Geologist, recently made the discovery of the ores and their value. New discoveries are being made daily, and 60 deposits have already been discovered."

PAPERS OF INTEREST TO TECHNOLOGISTS.

The following articles in the *Board of Trade Journal* for February 1891 will repay perusal:—

"Belgian Food Adulteration Law," p. 212, *seq.*

"Minerals used in Iron Smelting in India," p. 218, *seq.*

"The Indian Coal Fields," p. 222, *seq.*

THE GERMAN MATCH MANUFACTURE IN 1890.

(*A. Kolbe and Co. Chem. Ind.* 1890, 13, 470.)

No improvement is noticeable in this branch of chemical industry during the past year, partly on account of the high duties levied on the importation of matches made in Germany, into Austria and Italy, and partly because such countries as China, Japan, and South America have commenced to meet their own demand with native manufacture. In spite of this, new factories have been built in Germany, the proprietors being under the wrong impression that large profits could be made. The result is an over-production, which is certainly not a bright prospect for the future of the German match industry.—H. S.

THE PRODUCTION OF SUGAR DURING THE SEASON 1889—90 IN AUSTRIA-HUNGARY.

(*A. von Asbóth. Chem. Zeit.* 14, 1674.)

Two years have passed since the new duties on sugar came into force. The effect has been to almost double the production in Hungary. There is no fear of over-production, as the inland consumption has increased as well as the quantity exported. Lower freights in Austria and Hungary will enable the sugar manufacturers of these countries to cope with the competition from Germany. Export of refined sugar to Germany and through Hamburg has decreased, but increased to England, Italy, and through Trieste.

CONVENTIONS IN GERMANY.

The *Handelsmuseum* publishes an interesting abstract of a paper by Dr. F. Grossman on the "Cartelle," or syndicates, now in operation in Germany. From 42 at the end of 1887, the number of these organisations increased to 70 in 1888, and 77 in 1889. The year 1891 commenced with the formidable array of 116 existing syndicates, while 23 new ones were in course of formation. The iron, stone and pottery, and chemical industries are the worst afflicted. The last-named of these began the year hampered by 27 syndicates with 2 in course of formation. The leading Cartelle now extant, or which have been in operation, in this industry are:—The Stassfurt potash convention (established in 1879), the conventions in bromine (renewed for three years in 1888), Glauber salts (established 1882), sulphate of alumina and alum (established 1883), potashes (1886 to 1888, renewed in 1889), prussiate of potash (established 1886 with United Kingdom and Austria; from 1889 with Austria alone), and chromate of potash (Anglo-German established 1887); the German Salt Union and its offshoots (established 1886 and renewed in 1889 for ten years), the caustic soda convention (1883—88), the soda-ash union (established 1887), the rings in sulphate of ammonia (with Britain), borax (established 1886), boracic acid (established 1889), tartaric acid (1884 to 1887), sulphuric acid (established 1887), the Anglo-German convention in oxalic acid and oxalate of potash (1887 to 1890), the Anglo-Anstro-German convention in Uzan-dyes (established 1889); the corners in quinine (1883 to 1884), sulphonal (1888 to 1889), chloroform (established 1889), salicylic acid (established 1889), and iodine (American-European); the unions of German artificial manure makers (established 1887), phosphate works (established 1888), soapworks (established 1890), and vinegar-works (established 1890); the combinations in mineral oils (established 1885), paraffin candles (established 1887), ultramarine (established 1890), eating-oil (established 1887), gunpowder (established 1881), dynamite (established 1880, renewed 1889), and hunting-ammunition (established 1885); and the German petroleum import trust, dating from the commencement of 1891. It is difficult to see how any legislation could effectually suppress these outgrowths; but perhaps they, too, by teaching the advantages of co-operation to their members on the one hand, and affording to the public object-lessons in the evils of indirect taxation on the other, may actually "labour for some good, by us not understood."—*Chemist and Druggist*.

ALKALI MANUFACTURE IN RUSSIA.

The Russian Chemical Society has received a communication, with a sample of the first output of Russian bleaching-powder, from P. K. Ushkoff, of Elabouga (province of Viatka), who has just started manufacturing bleaching-powder on a large scale from native products. This is considered a very important step in the growth of Russian chemical industry, as the whole of the bleaching-powder required for home industries—about 10,000 tons per annum—is now imported from England. The same manufacturer has nearly completed his arrangements for manufacturing soda ash and caustic soda by the Leblanc process.—*Ibid.*

A MOUNTAIN OF PURE SILICATES.

A mineral discovery of unusual value is reported from Kamouraska, in Lower Canada. A Quebec correspondent states that an entire mountain has been found composed of silicates, otherwise known as vitrifiable stone, of a purity certified by the Provincial Engineer to average 98 per cent. This material is used for the manufacture of the finest glass, and is believed to exist nowhere else on the American continent in such purity. The Provincial Government has been asked by a deputation to guarantee 4 per cent. interest for 10 years on 20,000*l.* if a local company subscribes that amount to develop the new industry, and has promised to consider the request if the principal municipality concerned is prepared to take a fair share of the risk.—*Ibid.*

PROGRESS OF THE BASIC OR THOMAS-GILCHRIST PROCESS
DURING THE TWELVE MONTHS ENDING
31ST DECEMBER 1890.

The total make of steel and ingot iron from phosphoric pig during this period amounts to 2,603,083 tons, being an increase over the make for the previous 12 months of 325,531 tons, and making the total production of basic steel to this date, 13,148,000 tons.

Of the above-mentioned make of 2,603,083 tons, there was made by the basic Bessemer process 2,232,639 tons, and by the basic open-hearth process 370,441 tons. Of the basic Bessemer make 1,593,148 tons contained under 17 per cent. carbon, and of the basic open-hearth make 298,867 tons contained under 17 per cent. carbon.

The makes of the various countries for the 12 months ending 31st December 1890 and 31st December 1889 respectively are as follows:—

	1890.		1889.	
	Total.	With under 17 C.	Total.	With under 17 C.
England.....	503,400	551,404	493,049	348,828
Germany and Luxembourg.....	1,093,157	1,138,241	1,205,887	1,090,416
Austria.....	202,315	114,857	175,755	124,967
France.....	249,038	175,550	222,092	159,271
Belgium, Russia, and the United States.....	103,574	111,063	70,599	71,217
	2,603,083	1,892,015	2,271,552	1,764,639

With this 2,603,083 tons of basic steel there was produced some 623,000 tons of slag (containing about 36 per cent. of phosphate of lime), nearly the whole of which was used as a fertiliser.

ARTIFICIAL MANURES, &c. (ADULTERATION) BILL.

The objects of this Bill are—

(1) to make it compulsory in all sales of artificial manures or feeding stuffs to deliver to the purchaser a guaranteed analysis, and to place marks of identification on all packages of such manures and on all casks;

(2) to make misrepresentation of the nature and composition of manures or feeding stuffs punishable by summary process;

(3) to provide for the appointment of public analysts by county councils under the approval of the Board of Agriculture; and

(4) to enable county councils, with the sanction of the Board of Agriculture, for limited periods of time to employ the procedure of the Food and Drugs Acts in the detection and punishment of adulteration of manures and feeding stuffs.

The *Standard Agricultural Reports*, February 10th, 1891, summarises the Bill as follows:—

"In introducing a rough draft of Mr. Channing's Bill to prevent the adulteration of manures and feeding stuffs six weeks ago, we stated that the terms were not fully settled, and now that the Bill has been issued, we are glad to see that the defects noticed in the draft have been made good. The invoice certificate, which every seller of artificial manures or feeding stuffs in quantities not less than one hundredweight is bound to deliver to the purchaser, under penalty for neglect, and double penalty for misrepresentation, is to be a guarantee of the nature, origin, and composition of each commodity. The percentages of the several constituents of compound artificial manure must be given, and the percentages of the most important elements in other manures, as follows. Phosphate of lime and ammonia in raw or baled bones or bone dust, soluble and insoluble phosphate of lime and ammonia in dissolved bones, pure nitrate in nitrate of soda, soluble phosphate of lime in

mineral superphosphate, ammonia in sulphate of ammonia, phosphates calculated as phosphate of lime in guano, pure muriate in muriate of potash, sulphate of potash in kainit, and phosphoric acid equal to basic phosphate of lime in basic slag. Apparently the percentage of ammonia in the case of feeding cakes, the nature of the substance or substances from which the oil in the cakes has been derived, and the percentages of oil, albuminous compounds, and other constituents are required in the invoice certificate. Apparently cakes are the only feeding stuffs recognised; but the clause should embrace linseed meal and cotton-seed meal. The Bill proposes to empower county councils to appoint analysts, subject to the approval of the Board of Agriculture, and to pay them such remuneration as may be agreed, in order that they may analyse manures and feeding stuffs for purchasers at low fees. The county councils are also empowered to prosecute offenders under the proposed Act, and to appoint inspectors, subject to the approval of the Board of Agriculture, for the purpose of detecting cases of adulteration."

Monthly Patent List.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

957. H. Chilcott. Improvements in apparatus for intercepting and separating oleaginous and other matters from the water of condensation from surface condensers. January 19.

1040. A. K. Brown. Improvements in or connected with apparatus for softening and for clarifying liquids. January 20.

1043. C. R. Bonne. Improved machine for drying grains, corn, hops, chemicals, and like substances. January 20.

1071. R. Corcoran. A mixing machine for amalgamating exact proportions of flours, chemicals, and other substances. January 21.

1194. A. Chapman. Improvements in multiple effect evaporating apparatus. January 22.

1385. A. Haigh and J. Thewlis. Improved apparatus to be employed in the drying of animal or vegetable fibres. January 26.

1540. W. H. Webb. Improvements in or connected with compression pumps for gaseous or vaporous fluids. January 28.

1578. L. H. Armour. Improvements in or connected with ovens or furnaces used for the manufacture of hard coke, or for distilling shale, roasting ores, or otherwise subjecting carbonaceous matter to the action of heat. January 28.

1579. L. H. Armour. See Class III.

1585. S. Oates. Improvements in smoke-consuming apparatus and fuel economisers. January 28.

1629. W. R. Earp. Improvements in or relating to new or improved boiler anti-incrustation compounds or compositions and in the utilisation of waste substances for their manufacture. January 29.

1697. D. Guelbaum. Improvements in evaporation and distillation of liquids. January 30.

1846. J. King. Improved apparatus or multiple effect drying machine for drying, concentrating, or carbonising fertilisers, ochres, oxides, and other materials, and for concentrating and evaporating liquids, and for other purposes. February 2.

2083. C. H. Fitzmaurice. Improvements in apparatus and appliances for softening, purifying, and filtering liquids. February 4.

2099. E. Blass. Improvements in apparatus for treating materials by a circulating current of heated gases. February 5.

2141. W. T. Cotton and E. L. Garrett. An improved evaporator and surface condenser for producing pure distilled water. February 5.

2142. W. T. Cotton and E. L. Garrett. An improved apparatus for distilling water and other liquids. February 5.

2268. C. E. Miles. Improved means for evaporating liquids containing salts in solution. February 7.

2430. R. Cavanagh. Improvements in apparatus for charging liquids with gases. February 10.

COMPLETE SPECIFICATIONS ACCEPTED.*

1890.

1177. W. Sinclair. Composition for lining casks, &c. January 28.

2632. W. P. Thompson.—From A. Stehlik. Centrifugal apparatus for filtering liquids. February 18.

3907. R. Harvey. Evaporating apparatus. January 28.

3915. J. Schwager. Condensing apparatus. February 11.

4225. J. von Langer and L. Cooper. Valves for hot gases. January 28.

5142. E. Theisen. Apparatus for condensing vapours or gases. February 18.

5598. H. A. Fleuss. Freezing apparatus. February 18.

6951. C. Kellner. Lining boilers or digesters used in manufacture of paper pulp, and for similar purposes. January 28.

16,940. L. C. Riggs. Refrigerating apparatus. January 28.

18,751. O. Schulz. Continuous evaporating apparatus. February 4.

19,835. H. J. Allison.—From The National Salt and Chemical Company. Apparatus for the vaporisation of liquids. February 11.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

971. B. H. Thwaite. Improvements in methods of generating heating and lighting gases from liquids and solid hydrocarbons, and in apparatus therefor. Complete Specification. January 20.

1029. R. W. Papineau. Improvements relating to the manufacture and carburetting of gas, and to apparatus therefor. January 20.

1099. S. Geoghegan and M. F. Purcell. Improved apparatus for the purification and deposition of solid particles from gaseous fumes. January 21.

1237. A. L. Keller. A new fuel. January 23.

1386. J. Hargreaves. Improvements in the generation and combustion of gas for smelting and heating purposes, and in appliances connected therewith. January 26.

1410. J. Woodward. Improvements in machinery or arrangements for charging and drawing gas retorts. January 26.

1563. T. Clapham. Improvements in the construction of condensers applicable for use in the manufacture of illuminating or other gases. January 28.

1577. L. H. Armour. See Class III.

1682. J. Bowling. Improvements in coking processes. Complete Specification. January 29.

1866. J. Moeller. Improvement in lighting houses or any establishments through introducing into the pipes a mixture of gas and air to produce a "Bunsen" flame for lighting incandescent lamps. February 2.

1868. J. Moeller. An apparatus producing gas from light oils for lighting the so-called Welsbach incandescent gas lamps, and for general lighting purposes. February 2.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

1909. J. W. Ormiston, A. R. Ormiston, and J. Ormiston. Improvements in the manufacture and distribution of gaseous fuel, and in arrangements and apparatus therefor. February 3.

2021. P. F. Macallum.—From J. C. Ressig, Argentine Republic, and J. Landin, Sweden. Improvements in separating carbonic acid from other gases, especially in the production of calefacient gas for lighting and heating purposes, free, or practically free, from carbonic oxide. Complete Specification. February 4.

2098. N. Martin and B. D. Martin. An improved device for increasing the illuminating power of gas flames. February 5.

2145. G. Hargreaves, J. P. Seranton, and E. W. Porter. Improvements in apparatus for carburetting air. Complete Specification. February 5.

2158. A. Woosnam. Improvements in determining the illuminating power of gas and other flames. February 5.

2159. J. A. Soetje and J. C. A. Kahl. New or improved manufacture of briquettes, peat coke, and peat coke briquettes. February 5.

2170. H. Fourness. Improvements in the means and appliances used in the manufacture of illuminating and heating gases. February 6.

2193. D. Rylands. Improvements in fire-lighters and in the process of manufacturing the same. February 6.

2235. T. Williams. Improved combination or employment of ingredients for the manufacture of fire-lighters. February 6.

2452. U. André. Improvements in and connected with hydraulic mains for gas-making apparatus. February 10.

2736. V. Poltavtseff and K. Hodjaian. Improved means for generating heat from liquid and other fuel. February 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

3332. B. C. Sykes and G. Blamires. Separating hydrogen gas and the light carburets of hydrogen from water-gas or producer-gas, or both. January 28.

3684. T. Holgate. Method and apparatus for the manufacture of coal-gas and compounds of ammonia. February 11.

4197. H. L. Müller and W. Adkins. Apparatus for producing lighting gas. February 4.

4223. J. von Langer and L. Cooper. Production of water-gas and generator-gas, and apparatus connected therewith. February 18.

4324. J. A. Kelman. Apparatus for manufacture of gas. February 4.

5078. C. Hunt. Inclined gas retorts, and apparatus for charging same. February 18.

5163. S. J. Woodhouse. Method and means for charging and discharging gas retorts. February 18.

5194. G. Waller. Cooling and conveying coke discharged from retorts. February 18.

5453. W. Aekroyd, T. H. Aekroyd, and J. Willoughby. Method and apparatus for increasing combustion of smoke in furnaces, utilisation and transmission of heat, economising fuel, and improving draught. February 18.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

APPLICATIONS.

1308. C. M. Fielsticker. Improvements in the continuous distillation of hydrocarbon and other oils and liquids. Complete Specification. January 24.

1577. L. H. Armour. Improvements connected with coke ovens or other ovens, furnaces, or retorts wherein ammoniacal products, ligneous acids, and the like are obtained. January 28.

1578. L. H. Armour. Improvements in or connected with ovens or furnaces used for the manufacture of hard coke, or for distilling shale, roasting ores, or otherwise subjecting carbonaceous matter to the action of heat. January 28.

1579. L. H. Armour. Improvements in or connected with ovens, furnaces, or retorts used for the making of coke or charcoal, or for distilling or roasting carbonaceous matter, or otherwise subjecting carbonaceous matter to the action of heat. January 28.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

2242. F. Hlawaty. Preparing benzol, naphthalene, and anthracene from petroleum, petroleum scales, tar, tar oils, paraffin, &c., and from illuminating gas. February 18.

2955. H. Propfe. Process and apparatus for the continuous distillation of tar. February 11.

4120. J. Laing. Destructive distillation of mineral oils, and apparatus therefor. February 11.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

1001. R. Holliday and Sons, Limited, T. Holliday, and and P. R. E. Seidler. Improvements in the production or preparation of a new colour producing thiobase and of sulpho acids of the same. January 20.

1120. O. Imray. From The Farbwerke vormals Meister, Lucius, and Brünig, Germany. See Class VI.

1223. R. Hunt, E. S. Wilson, and E. Stewart. See Class XII.

1224. R. Hunt, E. S. Wilson, and E. Stewart. Improvements in the manufacture of colouring matters. January 23.

1354. O. Imray. From The Farbwerke vormals Meister, Lucius, and Brünig, Germany. Improvements in the production of a blue green and red violet colouring matter from alizarine blue. January 24.

1355. O. Imray. From The Farbwerke vormals Meister, Lucius, and Brünig, Germany. Improvements in the production of disazo colouring matters from the rosanilines. January 24.

1681. W. Cole. Improvements in the manufacture of indigo. January 29.

1737. O. Imray. From The Actien Gesellschaft für Anilinfabrikation, Germany. Improvements in the manufacture of colouring matters. January 30.

1742. S. Pitt. From L. Cassella and Co., Germany. Improvements in the manufacture of a new amidonaphtholsulphonic acid, and colouring matters therefrom. January 30.

1883. B. Willecox. From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture of new dyestuffs of anthracene and anthraquinone. February 2.

2682. I. Levinstein. A new or improved material for use in the production of colouring matters. February 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

3303. B. Willecox. From The Farbenfabriken vormals F. Bayer and Co. Manufacture of fast dyestuffs. February 4.

3788. M. G. Lindemann. Treating dyewoods and their extracts. February 4.

4382. B. Willecox. From The Farbenfabriken vormals F. Bayer and Co. Manufacturing new derivatives of phenyl-amido-acetic acid. January 28.

4577. O. Imray. From The Farbwerke vormals Meister, Lucius, and Brünig. Production of grey colouring matters. January 28.

4901. S. Pitt. From L. Cassella and Co. Manufacture of dyestuffs. January 28.

5723. B. Willecox. From The Farbenfabriken vormals F. Bayer and Co. Manufacture of phenacetine derivatives. February 4.

5777. O. Imray. From The Farbwerke vormals Meister, Lucius, and Brünig. Production of grey basic colouring matters by the action of hydrochlorate of nitroso-dimethylaniline, or hydrochlorate of nitroso-diethylaniline upon 1·5 dioxynaphthalin, and upon 1·2 tetroxy-dinaphthyl. January 28.

5780. O. Imray. From The Farbenfabriken vormals Meister, Lucius, and Brünig. Production of black colouring matters from amidollavopurpurine and amido-anthropurpurine. January 28.

6874. J. Y. Johnson. From The Badische Anilin und Soda Fabrik. Production of substantive colouring matters. February 1.

21,205. T. Peters. Manufacture of colouring matters. February 18.

1891.

583. J. C. L. Durand, D. E. Huguenin, and A. J. J. d'Andiran. Manufacture of new colouring matters. February 18.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

1426. W. P. Thompson. Improvements in or appertaining to the separation or purification of cotton seed from its adherent fibre, and also of other seeds or grains from external adherent matter or coating. January 26.

1616. F. L. Leech and A. Horrobin. An improved waterproofing solution. January 29.

1688. T. Craig, of the Firm of I. Holden and Sons. Improvements in means or apparatus for use in preparing and combing wool or other fibres to prevent waste. January 30.

1982. J. Kershaw, J. Wilcock, and A. Ashworth. Improvements in the treatment of textile fabrics, such as woollen piece goods. February 3.

2227. F. J. H. Sampson. Improvements in the treatment of reed and other vegetable fibre, and in apparatus to be used for this purpose. February 6.

2348. J. B. Barton. Improved process for the manufacture of granite linoleum. Complete Specification. February 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

3749. H. Blakeley and C. Beving. Ornamenting textile fabrics. February 11.

4452. H. A. Lowe. Treating materials from cotton or other cellulosic fibres. January 28.

21,230. J. W. Barker. Figured pile fabrics. February 11.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

1120. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Improvements in dyeing and printing on woollens azo-colouring matters derived from dioxynaphthalin sulphonic acids with metallic mordants. January 21.

1702. C. S. Bedford. New and improved methods of dyeing cotton and other fibres. January 30.

2533. H. Thies and F. Cleff. Improved process of dyeing or printing in aniline black. Complete Specification. February 12.

2604. P. G. Wild. A new or improved method of stamping and tinting textile fabrics, and apparatus for effecting same. February 13.

COMPLETE SPECIFICATION ACCEPTED.

1890.

12,379. H. H. Mott and J. Perry. Manufacture of decorative wall-papers. January 28.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

962. J. W. Kynaston. Improvements in the manufacture of sulphate of alumina. January 20.

1154. F. H. Gossage and J. Williamson. Improvements in or connected with the obtainment or manufacture of sulphur from sulphuretted hydrogen. January 22.

1168. M. N. d'Ardria. Improvements in the manufacture of barium chloride and strontium chloride. January 22.

1203. F. J. Jones. Improvements in the manufacture of sulphate of ammonia. January 22.

1226. R. Williams. Improvements in and connected with the utilisation of the impure sulphate of lead, known as "lead bottoms." January 23.

1261. O. Imray.—From La Société Anonyme des Anciennes Salines Domaniales de l'Est, France. Process for bleaching and purifying aluminium sulphate. January 23.

1453. E. O. Lambert.—From S. Pick, Austria. Improvements in the manufacture or production of salt from brine. Complete Specification. January 27.

1824. I. Lifschutz. An improvement in the process for the simultaneous production of cellulose and oxalic acid from vegetable fibrous substances. January 31.

1825. H. H. Lake.—From G. Letélic, Belgium. Improvements relating to the manufacture of carbonate of soda, carbonate of potash, hydrochloric acid, and chloride of lime, and to apparatus therefor. January 31.

2019. W. Walker. An improved process for obtaining silicates for making glass, and the production of hydrochloric acid. Complete Specification. February 4.

2134. J. Greenwood. Improvements in or relating to the manufacture or production of caustic soda. February 5.

2224. H. H. Lake.—From J. Massignon and E. Watel, France. Improvements in the manufacture of chromates, bichromates, and other chromium compounds. Complete Specification. February 6.

2252. P. G. W. Typke. Improvements relating to the manufacture or production of certain phosphorus compounds. February 7.

2343. T. G. Webb. An improvement in apparatus for concentrating sulphuric acid. February 9.

2499. W. C. Heraens. Improvements in apparatus for concentrating acids. February 11.

2611. J. Graham, G. E. Davis, and A. R. Davis. Improvements in the concentration of sulphuric acid, and in apparatus therefor. February 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

2296. J. C. Richardson and T. J. Holland. See Class XI.

2526. The Borax Co., Lim. Treating borates of lime and boracite for manufacture of borax and other borates. February 4.

2633. J. Leith. Distillation or treatment of ammonium chloride with Leblanc alkali waste, &c. January 28.

4434. J. J. Meldrum and T. F. Meldrum. Apparatus used in the distillation of ammonia. February 11.

4473. H. H. Lake.—From La Société Jpb. Jay et Jellatier. Apparatus for producing carbonic acid and similar gas. February 18.

4519. H. Precht. Production of potash from potassium and magnesium carbonate. February 18.

4759. H. Precht. Production of hydrate of magnesia. February 18.

5072. L. Mond. Treating phosphatic minerals. February 18.

8914. A. Crossley and J. W. Jones. Process and apparatus for producing ferro-ferrie and ferrie oxides. February 18.

16,049. R. Haddan.—From Viscount de Lambilly. Manufacturing alkaline or alkaline earth cyanides through atmospheric nitrogen, and application of same to the production of ammonia. February 18.

18,187. L. D. Armstrong. Apparatus for recovering soda and other chemicals from spent liquors. January 28.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

943. H. L. Doulton and S. H. Leech. Improvements in forming undercut projections and recesses in tiles and other articles of pottery, and in apparatus therefor. January 19.

966. E. Arthur. A composition for glazing or enamelling tiles, bricks, and like goods. January 20.

1222. W. W. Pilkington. Improvements in apparatus for forming molten glass into sheets. January 23.

1704. H. Warrington. Improvements in ovens or kilns for burning bricks, tiles, and the like. Complete Specification. January 30.

2019. W. Walker. See Class VII.

2668. E. Enderleine.—From Kreysler and Mohr, Germany. Improvements in the decoration or ornamentation of glass, china, and other ware. February 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

3343. T. Fletcher, R. Crag-Brown, and W. Ure. Brick and pottery kilns. January 28.

4504. E. P. Lee. Kilns for burning clay goods. January 28.

4509. D. Rylands and B. S. Shepeote. Machinery for manufacturing hollow glass-ware. January 28.

4792. D. Rylands and A. Hasselbee. Manufacture of glass-lined fittings for glass-lined piping. February 11.

6979. J. H. Lewis and J. Skidmore. Asbestos composition shadow for glass and other furnaces. February 18.

13,134. C. D. Abel.—From J. Meurin. Manufacture of bricks, slabs, pipes, pipe stones, &c. February 18.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

1115. W. R. Taylor. Improvements in and apparatus for the manufacture of cement. January 21.

1419. A. J. B. Ward. Fireproof floors, staircases, and roofs. January 27.

1617. J. G. Garrett. Improvements in kilns for burning Portland cement and other like substances. January 29.

1756. C. von Forell. Improvements in the manufacture of artificial Roman cement. January 30.

1753. G. F. W. Hope. Improvements in or relating to the production or manufacture of sand, chiefly for building and other purposes. January 30.

2017. J. McGlashan and E. H. Braidwood. Fireproof decorative material for ceilings, walls, woodwork, hangings, or upholstery. February 1.

2598. J. Ballantine. An improved medium or composition for decorative purposes. February 13.

2647. A. Lawrence. Improved means and apparatus for moulding artificial stone paving slabs. February 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

1176. W. Sinclair. Compound for cementing iron rails to stone kerbing, joints of stone, drain pipes, &c. January 28.

3133. W. G. Williams and S. Taylor. Ornamenting surfaces. February 11.

16,553. G. F. Relfern.—From W. Heller. Treatment of gypsum for building, statuary, and other purposes. February 18.

1891.

291. T. Potter. Fire-resisting concrete floors and ceilings combined. February 11.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

914. C. Billington, J. Newton, and C. Billington, jun. Improvements in the production of aluminium. January 19.

946. N. Lébédoff. Improvements in extracting iron or steel or other metals from ores or metalliferous materials. January 19.

950. H. H. Leigh.—From E. B. Heusmann, Germany. Improvements in metallic alloys. January 19.

978. I. Beardmore. Improvements in or relating to regenerative gas furnaces for steel melting, and analogous purposes. January 20.

1017. W. West. Improvement in apparatus for and process of treating zinc ores. January 20.

1161. B. H. Thwaite. An improved form of high temperature furnace especially adapted for the conversion of a high carbide of iron into the low carbide condition known as steel. January 22.

1197. J. Maclear. Improvements in the treatment of auriferous ores for the extraction of precious metal therefrom. January 22.

1208. H. H. Lake.—From J. H. Bevington, United States. An improved method of treating metal in the manufacture of tubes, and for similar purposes. Complete Specification. January 22.

1309. J. H. Pollok. Improved gold extracting reagents. January 24.

1374. A. M. Clark.—From La Société Anonyme de Produits Chimiques Etablissements Malétra, represented by F. E. Costes, France. Treating ores and residues containing zinc by means of bisulphate of soda for the production of commercial products. January 24.

1526. C. R. Aston. An improved method of utilising the calcined hot-blast stove and boiler-flue dust made in connection with iron-making furnaces. January 28.

1785. E. Meyer. Improvements in the production of aluminium. January 31.

1871. W. Ambler and H. Branter. Improvements in moulding hollow ingots and other tubular articles of molten metal. February 2.

1948. A. Birkbeck. Improvements in "tin-pots" or apparatus for coating metal plates or surfaces with tin or the like. February 3.

2000. P. Hart. Improvements in the treatment of composite ores containing zinc. February 4.

2049. E. Edwards.—From E. Honold, Germany. An improved process and apparatus for desilverising lead. February 4.

2089. J. Johnson.—From T. S. Blair, jun., United States. Improvements in the manufacture of steel. February 5.

2234. H. Parkes. Improvements in the manufacture of ferruginous alloys. February 6.

2326. A. P. Smith. Improvements in the separation of iron and nickel from solution of their sulphates. February 9.

2361. J. B. Alzugary. Improvements in metal alloys. February 9.

2508. A. de L. Long and J. Noble. A gas regenerative vertical ingot heating furnace. February 11.

2673. J. H. Darby. Improvements in the manufacture or purification of steel or homogeneous metal. February 13.

2722. J. H. Darby. Improvements in the manufacture of magnets, or of iron or steel, or the treatment of iron or steel for such manufacture. February 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1889.

17,627. H. H. Lake.—From S. H. Emmens. Production of ductile iron from cast iron. February 4.

1890.

2057. A. J. Campion. Processes and apparatus for smelting and treating tin ores, slags, slimes, and furnace débris containing tin, &c. February 18.

2544. J. W. Chenhall. Improvements in blast or smelting furnaces having water jackets. February 18.

3245. W. D. Bohn. Separation of gold and silver from ores. February 11.

3246. W. D. Bohn. Apparatus for separating gold or silver from ores. February 11.

4030. J. H. Darby. Manufacture of steel or iron. February 11.

5199. The Electric Construction Corporation, Limited, T. Parker, and A. E. Robinson. Treatment of copper nickel matte and obtainment of products therefrom. February 18.

5638. T. Teague. Extracting tin from slag or débris of tin smelting. January 28.

5641. H. Howard. Manufacture of iron and steel tubes. February 18.

16,545. H. H. Lake.—From O. B. Peek. Apparatus for decomposing metallic salts and desulphurising ores. February 4.

18,605. L. L. Burdon. Compound hollow metal lugots and wire. January 28.

18,636. R. Haddan.—From G. Conkling. Concentrating iron ore. January 28.

19,572. W. P. Hopkins. Manufacturing bar iron. February 18.

20,533. D. Brennan. Apparatus for crushing or reducing ores. February 11.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

1007. E. Ferraris. Apparatus for separating ores and metals by the aid of electricity. Complete Specification. January 20.

1035. S. W. Marquay. Improvements in primary batteries. January 20.

1049. S. Z. de Ferranti. Improvements in the manufacture of dynamo-electric machines. January 20.

1425. A. J. Boulton.—From W. Roberts, Canada. Improvements in storage batteries. Complete Specification. January 26.

1741. H. Howard. Improvements in electric welding, and in apparatus therefor. January 30.

1788. M. Bailey. Improvements in the construction of battery elements. January 31.

1818. J. B. Winder. A new or improved preparation of soluble bichromates and sulphuric acid for use in charging voltaic batteries and for other purposes. January 31.

2418. J. Matthews and G. B. Cruickshank. Improvements in electric accumulators or storage batteries. February 10.

2446. J. Y. Johnson.—From G. D. Davis, United States. Improvements in or connected with means or apparatus employed in electrolysis. February 10.

2471. T. W. Bush and M. Doubleday. The manufacture of hydrolysed lead cells for electrical or storage batteries. February 11.

2518. W. Gibbings. An improved method of depositing copper or other metals by electrolysis, with the object of refining it or them, or of recovering the precious and (or) other metals contained in or alloyed with the metal under treatment. February 12.

2654. Sir C. S. Forbes, Bart. Improvements in primary batteries. February 13.

COMPLETE SPECIFICATIONS ACCEPTED

1890.

1897. E. Fahrig. Composition for electrical insulating purposes, and manufacture thereof. February 4.

2273. G. R. Postlethwaite. Voltaic cells. February 11.

2296. J. C. Richardson and T. J. Holland. Electrolytic production of caustic soda, caustic potash, &c. February 11.

2297. J. C. Richardson and T. J. Holland. Apparatus for electrolytic purposes. February 11.

2945. A. M. F. Laurent-Cély and I. A. Timmis. Electric secondary cells, and manufacture thereof. February 4.

3028. A. C. Reigner. Dynamo-electric and electro-dynamic machines. January 28.

3967. J. S. Stevenson. Manufacture of secondary battery elements. February 4.

4384. J. Pitkin and H. C. L. Holden. Plates for secondary batteries. February 11.

5199. The Electric Construction Corporation, Limited, T. Parker, and A. E. Robinson. See Class X.

15,455. W. P. Thompson.—From C. L. Coffin. Welding metals electrically. February 4.

20,111. H. H. Lake.—From I. L. Roberts and T. H. McGraw. Apparatus for use in the electrolytic decomposition of metallic salts. February 4.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

963. P. R. de Fauchaux D'Huny. Improvements in the manufacture or treatment of soap for toilet, washing, medical, and other like purposes, and in apparatus for holding or containing soap, and supplying same for personal or other uses. January 20.

1223. R. Hunt, E. S. Wilson, and E. Stewart. Improvements in treating crude cotton-seed oil to obtain oil soap and colouring matter. January 23.

1997. A. Bruce, R. Harrison, J. Harrop, and A. Taylor. An improved washing compound. February 4.

2112. J. A. Clough. Improvements in or appertaining to the manufacture of soap. February 5.

2241. W. S. Somers. Improvements in refining oils and spirits, and apparatus therefor. February 7.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

1343. T. H. Gray and S. S. Bromhead. Retining linseed oil. February 4.

3601. R. C. Scott. Manufacture or shaping of soap. February 4.

5226. W. P. Thompson.—From R. Krause. Improved lanolin compound, and process for preparing and utilising same, specially applicable to the preparation of lubricants. February 11.

11,629. W. N. Hartley and W. E. B. Blenkinsop. Decolourising vegetable oils in the manufacture of pale drying oils and varnishes, and apparatus therefor. January 28.

19,960. P. Wild. Process and apparatus for smelting margarine, tallow, or other crude fatty substances by means of hot air. February 18.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

1127. R. C. Anderson. An improved manufacture of paints or varnish for coating leather, cloth, and other materials. January 21.

1145. J. Campbell. A new composition for coating tin and other like vessels. January 22.

1267. W. N. Hartley and W. E. B. Blenkinsop. The manufacture of an improved preparation of driers or siccativ material for mixing with paints. January 23.

2013. C. Schleich and E. Hanetzog. The production of permanent water-colours by means of blood serum. February 4.

2362. H. Wilcox, J. C. Butterfield, and T. C. Batchelor. Improvements in the manufacture of white-lead and other pigments, and in the by-products obtained therefrom. February 9.

2382. G. W. Seelay. Making paint or paint stock. Complete Specification. February 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

1178. W. Sinclair. Waterproofing and preserving composition for stone, bricks, plaster, and cement surfaces. January 28.

3786. G. Larrony. Manufacture of litharge and red lead. February 4.

11,629. W. N. Hartley and W. E. B. Blenkinsop. See Class XII.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATION.

1634. J. Sadler. Making an improved artificial leather. January 29.

COMPLETE SPECIFICATION ACCEPTED.

1890.

11,397. J. M. Pujos. Improvements in tanning. February 11.

XV.—AGRICULTURE AND MANURES.

APPLICATION.

2168. W. Bowler. Improvements in the collection and utilisation of excreta and in the preparation of manure therewith. February 6.

XVI.—SUGARS, STARCHES, GUMS, Etc.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

3240. A. A. Brehier and B. G. Talbot. Manufacture of artificial tartaric acids by means of cellulose, saccharine, or amylaceous substances. February 18.

5283. G. F. Redfern.—From M. Wienrich. Manufacture of sugar. February 18.

10,893. R. Pzillas. Apparatus for drying sugar or light substances. February 4.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

1244. A. G. Burkhardt and G. Schule. Apparatus for distilling and rectifying. Complete Specification. January 23.

2188. W. C. Marshall. Ascertaining the average specific gravity of unmixed worts at breweries and distilleries. February 6.

2241. W. S. Somers. See Class XII.

2294. H. H. Lake.—From G. Guignard and A. Hedouin, France. Improvements in and relating to the manufacture of alcohol, and in apparatus therefor. Complete Specification. February 7.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

4746. S. Joseph and H. Citron. Fermenting process in rarefied air-space. February 11.

6220. H. H. Lake.—From A. Joergensen and A. Bergh. Apparatus for the production of yeast and similar substances. February 18.

7195. J. Campbell. Process for the recovery and utilisation of yeast. January 28.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

2051. J. Y. Johnson. — From La Société Générale, Herscher and Co., France. Improvements in means or apparatus for sterilising water. February 4.

2055. G. D. Bowie. An improved phosphated salt as a food ingredient and for human and animal use. February 4.

2207. M. P. Hatschek, G. A. Clowes, and L. Briant. Improvements in the preparation of peptone extracts, and in the application of the same to various useful purposes. February 6.

2407. W. T. Thorp. New or improved foods. February 10.

B.—Sanitary Chemistry.

1225. H. Tatham. Improvements in and relating to the treatment of sewage and sewage deposits. January 23.

1998. W. F. Pinfold. An improved automatic mixer for preparing chemicals, to be applied in the purification of sewage or other liquids. February 4.

2117. C. H. Beloe and F. Candy. Improvements in and connected with the purification of sewage and other foul or impure liquids. February 5.

2169. W. Bowler. Improvements in the collection, disposal, and treatment of towns' refuse. February 6.

2729. J. E. Kierby. Improvements in apparatus for automatically regulating the supply of precipitating materials to sewage, and for other analogous purposes. February 14.

C.—Disinfectants.

1349. A. Findlay. An improved liquid or material for destroying insects. January 24.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1890.

2620. F. Grognet. Preserving meat, fish, &c. February 11.

3856. E. Leconte. Treatment or regeneration of yeast to be used in the process of bread-making, and preparation of paste and dough for pastrycooks and biscuit-bakers. January 28.

3995. G. Dosmond and F. Rozes. Process and apparatus for preserving meat and other alimentary substances. February 11.

19,178. O. Imray.—From The Mosquera Julia Food Co. Manufacture of ferments, peptones, and peptonised food products. February 11.

20,946. L. Breglia and F. Breza. Process and apparatus for preserving articles of food. February 18.

B.—Sanitary Chemistry.

1890.

1816. G. W. Ewens. Purifying the sewage of towns, and foul waters discharged from breweries, tanyards, glue-works, &c. February 11.

3312. W. E. Adency and W. K. Parry. Purification of sewage and other waste liquors containing organic matters. February 18.

C.—Disinfectants.

1890.

3628. F. Bale and C. Sims. Production of hydroxyl or peroxide of hydrogen, and apparatus therefor. February 18.

5113. J. Stilling. Method of destroying microscopic organisms for disinfecting, and substances used therefor. February 11.

XIX.—PAPER, PASTEBOARD, ETC.

APPLICATIONS.

927. R. N. Redmayne. An improvement in the manufacture of pulp for paper-making and other purposes. January 19.

1522. W. E. Bengel. An improved substitute for paper upon which to make water-coloured drawings. January 27.

2216. J. L. Lees. Improvement in writing-paper. February 6.

2349. J. C. Juel and E. Ryan. Improvements in purifying wood pulp, and in apparatus therefor. Complete Specification. February 9.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATION.

1271. H. W. Hart. Improved method of or process for treating coffee berries and producing an extract therefrom. January 23.

COMPLETE SPECIFICATION ACCEPTED.

1890.

5366. O. Imray.—From The Farbwerke Meister, Lucius, and Brüning. Production of guaiacol ether. January 28.

XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

APPLICATIONS.

1736. O. Imray.—From The Aetien Gesellschaft für Anilin Fabrikation, Germany. New or improved developers for photographic pictures. January 30.

1953. R. J. Winkoop and J. M. Kemp. Improved apparatus for use in photographic contact printing, a method of preserving sensitised paper, and a protective and adhesive solution therefor. Complete Specification. February 3.

2248. F. W. Verel and W. Hampton. Improvements in preparing, developing, and fixing photographic films. February 7.

2491. Marion and Co. (Leon Marion, G. Bishop, F. Bishop, J. P. Kirk, and H. Guibout). The storing and repeating the discharge of magnesium powder through a gas, oil, or spirit lamp, for use in spirit flash light photography. February 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

3393. E. W. Foxlee. Sensitised flexible film for photographic purposes. February 11.

14,189. V. Planchon. Films for use in photography. February 11.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

1054. R. C. Hanrott and S. D. Cox. An improved process for the production and purifying of peat charcoal for the manufacture of dynamite and other explosives. January 20.

1120. L. Errani and M. J. Berg. Improvements in the manufacture of matches. January 26.

2011. N. Erbsloh. A new or improved fuse for igniting the explosive charges of shells and other projectiles. February 1.

2246. H. D. Peckover. Waterproofing matches, explosive substances, fuses, &c. February 7.

2321. G. J. Meyer. Improvements in fireworks. February 9.

2656. O. Bowen. Improvements relating to the production of charcoal for the manufacture of gunpowder. February 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

2883. D. D. Esson. Fuses for projectiles. January 28.

3852. H. H. Lake.—From S. H. Emmens. Explosives. February 18.

5157. A. Noble and G. Stewart. Manufacture of pellets or plungers for percussion fuses. February 4.

20,978. H. H. Lake.—From G. M. Mowbray. Manufacture of nitrocellulose or pyroxylin. January 28.

THE JOURNAL

OF THE

Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 3.—VOL. X.]

MARCH 31, 1891.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2/6.

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.

COUNCIL FOR YEAR ENDING JULY, 1891.

President: E. Rider Cook.

Vice-Presidents:

Sir Lowthian Bell, Bart., F.R.S.	Ludwig Mond.
R. Forbes Carpenter.	Dr. Hugo Muller, F.R.S.
Prof. James Dewar, F.R.S.	B. E. R. Newlands.
James Duncan.	Dr. W. H. Perkin, F.R.S.
David Howard.	Dr. Edw. Schunck, F.R.S.
S. H. Johnson.	J. C. Stevenson, M.P.

Ordinary Members of Council:

A. H. Allen.	Prof. R. Meldola, F.R.S.
L. Archbutt.	E. K. Muspratt.
S. B. Boulton.	T. L. Patterson.
Jno. Broek.	Jno. Pattinson.
Jno. Calderwood.	Jno. Spiller.
H. Grimshaw.	T. W. Stuart.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Dr. Ferdinand Hurter.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

Sir F. A. Abel, F.R.S.	Prof. A. K. Huntington.
A. H. Allen.	F. Hurter, Ph.D.
L. Archbutt.	Ivan Levinstein.
G. H. Bailey, D.Sc., Ph.D.	Prof. R. Meldola, F.R.S.

NOTICES.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SCOTT-SWODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January and May 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

LIST OF MEMBERS ELECTED. 23rd MARCH, 1891.

Alexander, J. Dalziel, Dechmont, Cambuslang, near Glasgow, analytical chemist.

Aron, S. B. Asher, 44, Maryland Road, Maida Vale, W., metallurgical chemist.

Barnes, Edw. A., 57, Dekafield Road, Charlton, S.E., technical chemist.

Bayles, Dr. Jas. C., 63, John Street, New York City, U.S.A., president of Spital Weld Tube Company.

Boothby, Charles, 14, Palmer Street, Westminster, S.W., analytical chemist.

Brennan, J., 25, Bartons Bank, Aston, Birmingham, technical journalist.

Clarke, C. Goddard, Ingleside, Elm Grove, Peckham, S.E., wholesale druggist.

Cooke, Arthur Wm., c/o Brotherton & Co., Calder Vale, Wakefield, analyst.

Dyorkovitch, Paul, Ecclefield House, Seven Sisters Road, Finsbury Park, N., technical chemist.

Lalton, Jno. H. M., Ocala, Florida, U.S.A., analytical chemist.

Hanson, W. Banner, Kimberley Brewery, near Nottingham, brewer.

Hyde, Chas. E., 71, Higher Ardwick, Manchester, operative brewer.

Kitson, Sir James, Barta, Gledhow Hall, Leeds, iron and steel manufacturer.

Laing, Jno., 30, East Preston Street, Edinburgh, analytical chemist.

Lander, Albert H., 164 Edmund Street, Birmingham, metal merchant.

Lever, Jas. Darcy, Port Sunlight, near Birkenhead, soap manufacturer.

Lever, Wm. Heskette, Thornton Manor, Thornton Hough, Cheshire, soap manufacturer.

Loeffler, Geo. O., 153, Pearl Street, Pittsburg, Pa., U.S.A., analytical chemist.

Mellon, Edwin D., c/o Curtis, Davis, & Co., 184, Broadway, Cambridgeport, Mass., U.S.A., soap manufacturer.

Merry, Jas. S., 5, Richmond Villas, Swansea, assayer.

Robertson, Alex. A., Pentland Oilworks, by Leithhead, N.B., chemist.

Rowntree, B. Sechorn, The Cocoa Works, Yorks, cocoon manufacturer.

Smith, Irwin J., 2963 Wabash Avenue, Chicago, Ill., U.S.A., chemist.

Stewart, Chas., 14, Brechin Place, South Kensington, S.W.

Trubshawe, Wolstan, 6, St. Benet Place, London, E.C., merchant.

Turri, G. G., Sun Buildings, Queen Street, Melbourne, Victoria, patent agent.

Van Gundy, Chas. P., Eliza Furnaces, Pittsburg, Pa., U.S.A., analytical chemist.

Warburton, Thos., 2, Parhouse Terrace, Darby Street, Ardwick, Manchester, analytical chemist.

Ward, Alf. B., 88, Oakley Street, Chelsea, S.W., chemical expert in bread-making.

Wilson, Alex. Poole, 56, Bridge Street, Birkenhead, analytical chemist.

CHANGES OF ADDRESS.

Baker, Theodore, 1/o Dartford: Oakland, Bergen Co., N.J., U.S.A.

Beadle, Clayton, 1/o St. Mary Cray; 4, New Court, Lincoln's Inn, W.C.; Journals to Belvidere as before.

Carter, W. Chas., 23 (not 28), Eblana Street, Belfast.

Colby, Albert L., Journals to 131, South Center Street, Bethlehem, Pa., U.S.A.

Cooper, Arthur, Journals to Erdely, Middlesbrough.

Cornish, V., 1/o Pendleton; 134, Greenheys Lane, Manchester.

Edmunds, H. R., 1/o London; 24, St. Ann's Road, Wandsworth, S.W.

Forster, R. C., 1/o Newcastle; c/o Bessler, Waechter, and Co., 18-19, Fenchurch Street, London, E.C.

Galbraith, Wm., Journals to Highfield Road, Chesterfield.

Hall, Geo., 1/o Argentina; 7, Ogle Terrace, South Shields.

Hammill, M. J., 1/o Cressington; 125, Cooper Street, St. Helens.

Husband, J. Cecil, 1/o Manchester; Garston, near Liverpool.

Luck, Edw., 1/o Stamford Street; 68, Sumner Street, Southwark, S.E.

Luck, H. C., 1/o Stamford Street; 68, Sumner Street, Southwark, S.E.

Miller, Dr. Alex. K., 1/o Primrose Hill; 14, Osman Road, Hammersmith, W.

Peace, F. K., 1/o Sydney; Monton Grange, Eccles, Manchester.

Price, A. F., 1/o Post Street; 524, Sacramento Street, San Francisco, Cal., U.S.A.

Readman, Dr. J. B., 1/o India Buildings; 4, Lindsay Place, George IV. Bridge, Edinburgh.

Shuttlewood, W. B., 1/o Fenchurch Street; 8, Fenchurch Buildings, E.C.

Smaill, Wm., 1/o Montreal; c/o Londonderry Iron Co., Londonderry, Nova Scotia.

Smith, A. J., 1/o Ackers Street; 9, April Street, Upper Brook Street, Manchester.

Strype, W. G., 1/o Wicklow; 1, College Street, Dublin.

Thorneverott, W., 1/o Hamilton; 6, Dixon Street, Glasgow.

Trechmann, A. O., 1/o Hale; Norton Lodge, Stockton-on-Tees.

Wade, J. L., 1/o 30; 28, West Kensington Gardens, London, W.

Walker, Thos., Ecclestone Park, near Prescot (not Preston), Lancashire.

Wansbrough, E. G. L., 1/o Hampstead; 368, King Street West, Hammersmith, W.

Wilson, Jno., 1/o Redhough; 38, Windermere Street, Gateshead-on-Tyne.

Wright, Alf., 1/o Holloway; The Medical Hall, Yeovil.

Deaths.

Blake, F. C., of Pittsburg, at Helena, Mont., U.S.A., February 21st.

Crissy, W. G., East Orange, N.J., U.S.A., February.

London Section.

CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

Chairman: T. Tyrer.

Committee:

W. Crowder.

T. E. Thorpe.
C. R. Alder Wright.

Hon. Local Sec. and Treasurer:

T. W. B. Mumford, 1, Glendale Villas, Sylvan Road, Wanstead, E.

SESSION 1890-91.

April 6th:—

Election of five members to replace an equal number retiring from Committee. Nominations to be sent to the Hon. Secretary on or before Monday, March 24th.

Professor Vivian B. Lewes:—

1. "The Analysis of Illuminating Gases."
2. "The Products of Checked Combustion."

April 20th.—Mr. W. P. Rix. "Stoneware; and its Application to Chemical Apparatus."

May 4th.—Mr. L. Archbutt and Mr. R. M. Dooley. "An Improved Process for Softening and Clarifying Water."

June 1st.—Dr. W. S. Squire. "The Artificial Production of Cold theoretically and practically explained."

Meeting held Monday, February 2nd, 1891.

MR. THOS. TYRER IN THE CHAIR.

ON STANDARD SPERM CANDLES.

BY W. C. YOUNG, F.I.C., F.C.S.,

Gas Examiner to the Corporations of London, West Ham, Hastings, and Bedford, and to the Carshulton Local Board.

A COMMON expression used in reference to sperm candles as standards of light for coal-gas is, "I get very good results when they are properly used," but it is very difficult to get a clear definition of what constitutes the proper method of using them. During the 30 years sperm candles have held the position of legal standards of light several attempts have been made to abolish them, none of which have yet been successful, and as in all probability they will continue the standard of comparison for some time to come, it is desirable to ascertain if it be possible that they can be so used as to give practically uniform results. Experienced photometrists, even those who have been foremost in condemning sperm candles, agree that by careful use fairly reliable results may be obtained with them, especially when an average of several experiments is taken. This being so one would, of course, expect that the Metropolitan Gas Referees, who were constituted eight years after the sperm candle standard was legalised, would, in their half-yearly notification, give such directions for using candles as would ensure uniformity of method and reliable results. On referring to these official documents I find that for some years all that they contained was the following: "The candles are to be lighted at least 10 minutes before the

beginning of each testing so as to have arrived at their normal rate of burning, which is shown when the wick is slightly bent and the tip glowing." In 1877 this direction was altered to the following: "The candles are to be lighted at least 10 minutes before the beginning of each testing, so as to have obtained their normal rate of burning." It would seem that at this date the Gas Referees were of opinion that it was sufficient for the purpose if the candles had been lighted 10 minutes, leaving it to the judgment of the gas examiner to decide whether they were in a fit condition to use or not. In this year the Gas Referees also ordered that all testings were to be rejected where the candles burnt more than 126 or less than 114 grains per hour. In 1889 (13 years after I first called attention to the matter) some notice is taken of the circumstance that the flames of the candles are central only when the wicks are in a certain relative position, and that they are continually shifting their positions, by the insertion in the notification of directions intended to overcome this difficulty, and for the first time the gas examiner is required to use a different candle for each testing in the day's work.

I need scarcely say that even the latest directions of the Gas Referees are insufficient to ensure uniform results, and that a difference of at least a candle is of frequent occurrence in practice.

I have used sperm candles for testing gas daily for 23 years, and have devoted much attention to them for the purpose of ascertaining the causes of their defects and the means of remedying them. From time to time since 1876 I have stated, in the correspondence column of the "Gas Journal," my opinions on the subject, and in Vol. 52, p. 207, will be found a letter in which I detail the mode in which candles should be used so as to give fairly uniform results. The mode there stated is as follows:—

1. They should have been burnt until the tips of the wicks glow, blown out and allowed to cool, at least three times before use.
2. The tips of the wicks should be not more than three-eighths of an inch from the top of the candle.
3. They should never be allowed to burn more than 15 or less than 10 minutes before use.

I had arrived at this method by observations made in the discharge of my official duties as gas examiner, with the addition of special experiments made from time to time as occasion arose, but up to that date I had not made any systematic investigation of the subject. Seeing the great necessity of such an investigation I commenced a long series of experiments, the results of which form the substance of this paper.

At the outset I experienced great difficulty in devising some means by which a uniform volume of light could be conveniently produced at any moment for the purpose of testing the candles with, but ultimately, by means of a simple apparatus applied to the London Argand burner, prescribed by the Gas Referees as the test burner for the Metropolis, I succeeded fairly well. This apparatus consists of a screen of fine wire gauze fitted tightly to the outer rim of the gallery of the burner, and extending three or four inches below, the bottom being closed by resting on the bottom of the photometer case. In this way the currents of air supplying the burner are equalised, with the result that the flame burns, in a good burner, with a perfectly even top, so that it can easily be measured, up to 2·8 in., to within a tenth of an inch. Flames above this length become uneven, rendering exact measurement almost impossible. This little apparatus will be found of great assistance when it is desired to read the length of a flame, and can be obtained of Messrs. Sugg and Co.

After a few preliminary experiments I found a 2½-in. flame the most promising for my purpose, and accordingly I adopted that length of flame in all the experiments to be described; a modified Evan's, in which the disc was stationary, being the photometer employed. The temperature of the room varied, throughout the experiments, between 58° and 68° F., strict cleanliness in regard to the candles being constantly observed.

candles with the wicks carefully trimmed and regulated as I have just described. Six candles were taken, of the same make as those previously used, and eight tests, or as many as possible, taken with each. The following results, stated in the order in which they were taken, were obtained :—

14'21 = mean.		14'22 = mean.		14'21 = mean.	

It will at once be seen from these results that the figures obtained are much closer than in the former experiments, and that the enormous variations disappear. I think it worthy of especial notice that the mean results obtained with each candle is practically the same, showing that, at any rate with this particular make of candle, really uniform results may be obtained if the mean of eight tests with one candle be taken when the precautions I have indicated have been observed.

In all the foregoing experiments the same make of candle was employed. In order to ascertain whether other varieties would give similar results, I obtained samples of the candles used for the official testings at various provincial gasworks whose gas I have to test periodically for the local authorities, and from other sources, and tested them against the $2\frac{1}{2}$ -in. flame, having previously trimmed and regulated the wicks. The results are stated consecutively in Table IV.

SAMPLE D.

14'33 = mean.		14'18 = mean.		14'24 = mean.	

NOTE.—The tests with sample E. candles were commenced with a fresh graduated chimney, the one used in all the previous experiments having unfortunately been broken, when the first tests with the three candles gave results 14'24, 14'21, and 14'04 respectively. These results being abnormally high, my suspicions were raised as to the correctness of the graduations on the chimney. On testing these I found they were placed nearly a tenth of an inch too high. The chimney was therefore rejected, and another, correctly graduated, taken, which was used in all the succeeding experiments.

SAMPLE F.

Wicks contained 21 threads in each strand.

13'98	39'5	13'99	39'3
14'36	39'1	14'18	39'0
14'10	39'1	14'27	39'1
14'43	37'7	14'34	40'4
14'19 = mean.		14'18 = mean.	

The candles employed in the foregoing experiments comprise, as will be seen, a variety of makes, as indicated by the number of threads in the wicks, yet the results obtained are practically the same with each variety, the mean results being remarkably close to the mean value given to the gas flame. I may point out that the consumption of sperm appears to bear little relation to the number of threads in the wick, and that the candles with the least burnt the largest quantity. It is therefore evident that the consumption of sperm is affected more by the manner in which the wick is plated than by the number of threads it contains.

On comparing the results obtained with the sperm burnt, these experiments will be found to show very clearly that the quantity of sperm consumed has little or no effect upon the result; or in other words, that the light given by the candle is fairly proportionate to the sperm burnt within the ranges shown. The highest consumption of sperm was 45'4 grains in 10 minutes, and the lowest 36'3, the values given to the gas flame being 14'24 and 14 respectively.

At this stage of my paper it will be instructive to consider the bearing which these results have upon the methods at present in use at the metropolitan testing stations with regard to candles. Up to April 1889 the Gas Referees permitted the gas examiners to use the same candle for the three daily tests, the average of which represents the illuminating power for the day, but since that date they have ordered that different candles shall be used for each test. The effect of this is that two gas examiners testing the same gas may obtain totally different results, for if one works with three fresh candles he may report the gas as a candle and a half higher than another who employs candles that have already been used several times. Under the old regulations a better average of the candle was possible, and as a consequence disputes were less frequent. I have also shown that the restrictions imposed of late years by the Gas Referees as to the sperm burnt by the candles are quite unnecessary.

On comparing the method adopted with the candles in the experiments recorded in Tables III. and IV. with that suggested in my letter to the "Gas Journal" (vol. 52, p. 207), it will be noticed that I omitted in the former to burn the candles three times to a glowing wick before using them, but commenced testing with them as soon as the wicks were smooth and burnt with a bright glowing tip. I did this in order that as many tests should be obtained with each candle as in the previous experiments, where no precautions were taken beyond waiting until the tips of the wicks glowed before commencing.

My next experiments were made in accordance with the suggestions in the letter referred to, and the wicks were further assisted to burn into proper condition by gently

A

B

C

bending them downwards when necessary and removing all loose fibres. The candles were all of the same make as those used in the experiments recorded in Tables I. to III. Six tests were made with each candle, that being as many as could conveniently be obtained, and at least an hour's interval elapsed between any two tests with the same candle. The results, stated in consecutive order, were as follows:—

TABLE V.

No. 1 Candle.		No. 2 Candle.		No. 3 Candle.	
Result in Candles burning 120 Grs. per Hour.	Grains Sperm burnt in 10 Minutes.	Result in Candles burning 120 Grs. per Hour.	Grains Sperm burnt in 10 Minutes.	Result in Candles burning 120 Grs. per Hour.	Grains Sperm burnt in 10 Minutes.
13.94	40.3	14.38	39.9	14.36	39.8
14.03	42.5	14.12	40.0	14.42	39.2
14.34	42.0	14.08	39.1	14.02	38.3
14.32	41.4	14.24	41.7	14.47	39.7
14.35	43.7	13.94	41.0	14.02	41.0
14.24	41.6	14.11	40.5	14.25	40.2
14.20 = mean.		14.14 = mean.		14.25 = mean.	

No. 4 Candle.		No. 5 Candle.		No. 6 Candle.	
Result in Candles burning 120 Grs. per Hour.	Grains Sperm burnt in 10 Minutes.	Result in Candles burning 120 Grs. per Hour.	Grains Sperm burnt in 10 Minutes.	Result in Candles burning 120 Grs. per Hour.	Grains Sperm burnt in 10 Minutes.
13.98	39.2	14.03	41.7	14.37	41.6
14.00	39.5	14.08	41.8	14.28	41.1
14.01	40.8	13.98	41.4	14.22	40.8
14.26	41.0	13.99	41.9	14.48	41.8
14.18	41.0	13.94	40.3	13.91	43.6
14.18	40.7	Lost.		14.20	42.6
14.10 = mean.		14.00 = mean.		14.24 = mean.	

These results are even less variable than those recorded in Table IV., and the several means equally uniform, showing that in this way the number of tests necessary to ensure a reliable result may be reduced to six.

If this method were adopted (with an average of six tests) at the public gas-testing offices it would, of course, double the work required of the gas examiners, but a further examination of the results will show that an average of three tests by this method gives equally satisfactory results. The tests, as regards the position of the wicks in relation to each other, and the interval elapsing between each test, were all taken in accordance with the Gas Referees' recent notifications, and assuming that they were the official tests for the several days, the results would be recorded as follows:—

1st day	14.23
2nd „	14.19
3rd „	14.15
4th „	14.34
5th „	14.10
6th „	14.20
7th „	14.13
8th „	14.12
9th „	14.07
10th „	14.24
11th „	14.01
12th „	14.19 (mean of two tests)

showing a maximum variation of only a third of a candle in the illuminating power of the gas flame in 12 days' work. It may reasonably be supposed that the $2\frac{1}{2}$ -in. gas flame employed varied slightly in illuminating power from time to time, but even if it is assumed to have been absolutely invariable, and the whole of the differences in the results attributed to the candles, these experiments prove that sperm candles can be so used as to give very satisfactory results.

Candles as a standard of light have got into bad repute through being looked upon as a rough and ready measure, instead of being treated as a scientific instrument. My suggestion (the outcome of these experiments) is that they should always, before use, be brought into a uniform condition as regards shape and state of the wicks. Opinions may differ as to what that shape should be, but all will agree that the wicks should be clean and free from loose fibres. The shape I have adopted is that which they naturally assume, in the majority of cases, after the candles have been burnt and extinguished three or four times, and which enables them to be properly consumed, as the ash flies off in sparks and does not accumulate on the tips, and prevents the deposition of soot. This shape is also generally retained as long as the candles last, if they are burnt only long enough for the tips of the wicks to glow before commencing a test, which is from 10 to 15 minutes, and are extinguished by blowing out immediately the test is completed.

The accompanying photographs illustrate, more clearly than I can describe, the shape of wick I advocate.

A shows the shape of the wick for the first two or three times of using a candle, if allowed to burn without interference, and is the condition which gives variable and unsatisfactory results.

B and C show the shape of wick I advocate.

In the discharge of my duties as gas examiner I have noticed that, although I could get very uniform results in tests taken immediately following each other (when the chimney on the burner was not changed) with candles used as in the experiments last described, yet tests taken with intervals between each of at least an hour gave results not always as uniform as I expected from the length of the flames. I was not surprised at this when the flames approached or exceeded 3 inches in length, as I have already stated that above 2.8 in. it is difficult to read the length exactly, but with 2.7-in. flames one would expect uniformity in results, and I have occasionally failed to get it. In all my experiments with $2\frac{1}{2}$ -in. flames only two different chimneys were used, these were of the same colour, thickness and dimensions, and invariably placed in the same position on the burner so as to present the same face to the photometer disc in each experiment. In my daily official tests a different chimney was always used for each. It occurred to me that the discrepancies might be due to the chimneys. On examining my stock I found they were all of a smoky brown colour, and varied very much in thickness. They varied also in internal diameter, and not one was perfectly cylindrical, all being wider at one end than at the other.

I made a number of tests immediately following each other with thick and thin chimneys, varying in thickness from $\frac{1}{8}$ to $\frac{1}{16}$ of an inch, taking especial care with the candles. The results are below:—

No.	Thick.	Thin.	No.	Thick.	Thin.
1	15.53	15.93	8	15.43	16.36
2	15.94	16.68	9	15.98	16.56
3	15.48	16.28	10	16.06	16.63
4	15.85	16.53	11	16.34	16.83
5	16.09	16.65	12	16.17	16.68
6	16.08	16.50	13	16.10	16.55
7	16.77	17.48			

These results show very conclusively that the thickness of the glass had a considerable effect on the illuminating power, and in order to see if the colour of the glass had anything to do with it, I made comparative tests with thick and thin brown glass, and thick very pale amethyst glass chimneys. The amethyst chimney was thicker than the thickest brown one, but was more cylindrical. The results were as follows:—

No.	Thick Amethyst.	Thick Brown.	Thin Brown.
1	16'24	..	16'48
2	16'60	15'25	..
3	16'42	15'85	..
4	16'79	16'02	..
5	15'90	15'68	16'42
6	16'24	15'65	16'47

These results show that the colour of the glass had a most important effect on the light of the flame, and should not be disregarded when accurate work is to be done. The thickness of the glass also, apart from the colour, appears to be of importance. It seems probable that the light of the gas may be further influenced by the diameter and shape of the chimney, but I have not had time to put the matter to the test. Where the dimensions of the test burner are stated in an Act of Parliament the height and diameter of the chimney are given, but none of those Acts with which I am acquainted states whether the internal or external dimensions are to be taken, or if it should be perfectly cylindrical. It seems to me that the internal measurement is the only proper one to take, and the Gas Boards also take this view, but recently, in a dispute on this point in the provinces, the makers of the burner, Messrs. Sugg and Co., contended that it should be the external. The subject is most important and calls for more attention than it has hitherto received.

On completing these experiments I proceeded to make my daily official tests, using the same chimney for each and marking it so that I could always ensure placing it on the burner in the same position. The candles were treated as in the experiments recorded in Table VI., and the length of the gas flame taken immediately before the commencement of each test.

I may mention that an official of the gas company was present at each test. I give below the results of each test for 18 days:—

TABLE VII.

Official Tests taken at the City of London Testing Station,
3, Jewry Street, Abgate.

No. of Candles.	Result in Candles burning 120 Grs. per Hour.	Grains Sperm burnt in 10 Minutes.	Approximate Height of Flame.	Date.
			Inches.

Taking into consideration the fact that the heights of flames recorded are only approximate, and that a difference of a tenth of an inch in the flame more or less must greatly alter the light, I think, with only three or four exceptions, these results give favourable evidence for candles as a

practical standard of light. Taking the results in the order of the heights of the flames they appear as follows:—

2·9-in.	3-in.	3-in.	3·1-in.
16·06	16·20	16·16	16·39
16·07	15·94	16·10	16·08
16·04	15·78	16·22	16·17
15·84	15·98	15·96	16·08
15·78	15·78	16·30	16·54
15·84	15·70	16·15	16·72
16·02	16·24	15·94	16·50
15·77	16·24	15·63	16·63
15·81	16·03	16·24	16·30
15·76	16·04	16·09	16·50
15·66	15·87	15·98	16·38
16·14	15·80	16·03	16·12
..	16·00	16·54	..

	2·9-in.	3-in.	3·1-in.
Percentage of results close to 1 per cent. of mean.	83·3	76·9	50

There were in addition one instance of a 2·8-in. flame, and three of 3·2-in. flames, the results being 15·3 and 16·84, 16·74 and 16·81 respectively.

Viewed in this way, the results seem to indicate that the variations are not due to the candles, but attributable to the difficulty of exactly measuring the flame. I have already stated that the longer the flame the more uncertain the measurement becomes, and this table shows that with the shortest flame (2·9 in.) the results are most uniform and with the longest (3·1 in.) least uniform.

Two days after the date of the last tests mentioned above, my station was closed for alterations, and on those days I varied the proceedings by using the same candle for each test, the results being as follows:—

Result in Candles burning 120 Grs. Sperm per Hour.	Grains Sperm burnt in 10 Minutes.	Approximate Height of Flame.	Date.
16·60	40·3	Inches. 3·2	11 April.
16·80	40·0	3·2	"
16·59	40·6	3·2	"
16·62	39·9	3·2	12 April.
16·90	39·3	3·2	"
16·70	39·1	3·2	"

I think I have shown conclusively: 1st, that standard sperm candles may be relied upon to give fairly uniform results if due regard is paid to the condition and shape of the wicks before commencing an experiment; 2nd, that the light they give is practically proportional to the sperm burnt far outside the limits fixed by the Gas Referees; 3rd, that the number of threads forming the wicks within certain limits is immaterial; and 4th, that the glass chimneys used with the test burner should be uniform in colour and thickness in order to obtain accurate results.

In conclusion I may mention some experiments I have made with one of the latest proposed standards of light, viz., Harcourt's 16-candle standard. In the early part of this paper I stated that I had found that, 2½-in. flames in

the 16-candle test burner of coal-gas, carburetted coal-gas (i.e., coal-gas passed over cold petroleum spirit as in Lowe's carburetter, or hot as in Maxim's) and of Pintsch's oil-gas, all possessed the same lighting power, but that a similar length of flame of Steinberg's carburetted water-gas, of a mixture of coal-gas and carburetted water-gas made by Meeze's process and of coal-gas enriched with petroleum oil instead of cannel coal, as in Good's patent (in which the petroleum is injected into the gas retorts when the charge is nearly exhausted), gave much higher results. My experiments show that with Steinberg's gas the 2½-in. flame equals 18 candles, with coal-gas and Meeze's carburetted water-gas 16·4 to 17·4 according to the proportion of the latter present, and with gas obtained by Good's method, 15 candles.

In view of the fact that carburetted water-gas is now being made and supplied in England either alone or mixed with coal-gas, it is important to know whether standards of light such as the one under notice are affected by the substitution of such gas for common coal-gas.

Harcourt's 16-candle standard consists of a London Argand burner over which a screen is fixed at a definite height above the top. The gas is turned on at the rate of 4·5 cb. ft. per hour, and sufficient of the gas is then passed through a carburetter containing pentane to produce a flame about 3 in. in length which is shown by the tips of the flame appearing at a peep-hole provided in the screen for the purpose.

By the kindness of Mr. Heisch, who lent me the Harcourt's standard, and of Professor Lewes, who placed at my disposal the gas and photometer at Steinberg's carburetted water-gas works at Knights-bridge, I was enabled to test the standard when burning carburetted water-gas. The apparatus was set up in the photometer in place of the test burner, and tested against candles. The gas used was of a value of 18·2 candles. Two tests were taken with the following results:—1st = 17·58, 2nd = 17·8 candles instead of 16 candles. Therefore gas of this character possessing an actual illuminating power of about 17·7 candles, when tested by this standard, would be returned as only of 16-candle power.

It is evident, from the result of these experiments, that this proposed standard would be quite unsuitable for testing carburetted water-gas or coal-gas mixed with it in any proportion.

Lowe's jet photometer also gives equally erroneous indications with carburetted water-gas. With a mixture of coal-gas and Meeze's carburetted water-gas I have on several occasions found the jet photometer indicate 16 candles when the quality has really been over 18.

I have no doubt that all other standards of light in which the gas under examination is employed, such as Methven's and Sugg's 10-candle standard, would be found to be affected in the same way, and I hope shortly to have an opportunity of making an exhaustive series of experiments in this direction.

DISCUSSION.

The CHAIRMAN having invited discussion—

MR. W. J. DIBDIN said that the facts so ably brought before the Society by the author would have an important bearing upon the future settlement, if ever it came about, of the vexed question of standards of light. Mr. Young had shown that it was quite possible, by means of sperm candles, to obtain definite and constant results. He himself had been able to obtain similar results. The difficulty in his case was not what candles could be made to do if he was allowed to use his own discretion in employing them, but what they would do in his hands when he was tied down by the red tape of Acts of Parliament and the instructions of authorities—instructions no doubt given in good faith, but limited by the terms of an Act of Parliament. The lawyers with whom he was sometimes associated in this matter frequently met his statements with the remark, "Yes, your science is no doubt good, but it is the law that we have to deal with." He had found that, as a rule, science had to take a very minor place in a police court, and in his experience of those unwholesome places he had frequently been made to feel very small when questions

arose involving matters of scientific accuracy. That difficulty was well illustrated in a case relating to the testing of petroleum which had come under his notice. The gentleman who had made the test had omitted to swing the string with a bob at the end, which oscillated while the test was made, and he was honest enough to admit that he had not set it swinging, but said that he did not think it would make any difference to the result. Counsel, however, contended that he had not complied with the Act, and the case was dismissed. And it was the same with them in the matter of candle tests. Therefore it was that they complained of candles as a standard of light, *i.e.*, of candles in their legal aspect. In the laboratory, where the chemist was allowed to use his common sense, much better results were obtained. But then arose the question from the point of view taken by Mr. Young. He would say that process A was a proper one to use. On the other hand, the gas companies would probably object that the results were abnormal, that he had not burnt the candles in the right way; and they would ask that they should be burnt in some other way, so as to give results, say, of 17 candles. He did not blame them. It was a question of two parties having hold of the two ends of a piece of elastic and fighting the question of which was the fixed end and which the moving. That, he thought, summed up the candle controversy. They could work the candles better than they were obliged to do by the Act, and they must endeavour to get an alteration of the Act and more definite instructions. That, however, raised the question whether it would not be better at once to get a new Act of Parliament, which should prescribe a definite and invariable standard that could be worked in only one way. If they used a standard gas, they would have checks on the operations of the examiner, inasmuch as they would know the rate of flow of the gas and the height of the flame. Taking the broad facts of the paper, Mr. Young had told them that a 2½-in. flame from a standard argand burner was equal to about 11·2 candles. In listening to the statements about the 2½-in. flame, the question had occurred to him whether Mr. Young's or the other figure of 16 to 17 candles were the correct one. He was therefore rather sorry not to hear from the author a few comparisons between candles used in the way he proposed and one of the recognised substitutes for candles as a standard of light. Mr. Young had not given any evidence that his method of using the candles was correct, nor any reference to the Parliamentary standard candles. That was an omission which he hoped that the author would take the first opportunity of supplying, for everything depended on whether Mr. Young's figure or the higher figure were correct. Most of the gas people, he thought, would maintain that 11·2 could not possibly be correct. Mention had been made of the German method of using a standard candle. He would, however, remind the author that the Germans did not use a sperm candle, but a paraffin one. They had experienced precisely the same troubles in Germany, and were not out of them yet; in fact in some respects they were waiting to see what course would be taken in England. Germany had appointed a Royal Commission to inquire into all the vexed questions that we were now troubled with in connexion with standards of light. They had decided that it would be best to have a standard paraffin candle manufactured under the immediate supervision of the authorities and sent out in sealed packets, the candles being so marked by a red thread as to be easily identified as genuine standard candles. But the Germans went further; they measured the height of the flame, and if they were not satisfied with its character, they snuffed the wick. That was a practice that in England would be regarded as most objectionable, it being held that the examiners should do nothing which might bias the results. He was reminded of the German practice when listening to the author's statement of how he thought it right to virtually snuff his wicks by burning, blowing out, relighting, and repeating the operation several times, taking care meanwhile that the wick was not bent down too much. They used to know the normal curve of the wick, and the conditions under which they could get satisfactory results. Still, there always remained the initial difficulty—where to fasten the piece of elastic—which position of the wick should be

taken. They had, it was now contended by the gas companies, to use the wick, not vertical, but approaching the vertical. That was, in the companies' opinion, the normal candle, and one with a gentle curve was abnormal, because it gave results which were too low. They were, therefore, as far off as ever from a settlement of the question from the candle point of view, and must approach it by some other means. Mr. Young was, he thought, entitled to great credit from a scientific point of view for the information which he had put before them. It was to be regretted that he had not given some definite comparisons of his results with those of known standards; and if he now supplied that omission the value of his contribution would be greatly increased. With regard to the 16-candle argand introduced by Mr. Harcourt, Mr. Young had shown that in using some of the gases which were proposed to be introduced into London, the standard would be no longer reliable. That was an interesting point, but in connexion with it he would like Mr. Young to try the pentane argand which he (Mr. Dibdin) had had the honour of bringing before the Society, in which the standard combustible was absolutely separate from the gas to be tested. This proposed standard, which he had called the pentane argand, was simply a small argand specially constructed to burn a combustible consisting of common atmospheric air charged with vapour of pentane. The use of atmospheric air did away with all the uncertainties of coal-gas. It was perfectly reliable and easily obtainable, and it was equally useful for testing electric lights or oil burners. He had never put it forward in preference to the one-candle pentane flame, but he was sure that if Mr. Young tried it, using atmospheric air and pentane, and keeping his carburettor properly charged with pentane, he would not fail to obtain results of a very satisfactory nature.

Mr. W. Foster said that if, as he understood, Mr. Young proposed to use an argand burner with a metallic gauze round the base for testing various carburetted gases, it would be interesting to have before them a sketch—even of the roughest nature—of the apparatus to be employed.

Mr. Youso, interposing, said that he thought Mr. Foster had missed the point with regard to that matter. The burner used was the ordinary test burner in the photometer, and the gauze curtain was simply to steady the flame,—to enable him to produce a 2½-in. flame—which he had found to possess a practically uniform lighting power, to test his candles against, and not for the purpose of testing any particular gas.

Mr. Foster replied that he merely wished to know whether the air passed through the gauze, and what was the position of the gauze in relation to the burner.

Mr. Youso said that it was a cylindrical curtain fitting tightly round the outer gallery of the burner.

Mr. Foster: Then the air passes through the gauze?

Mr. Youso: Yes, all the air passes through.

Mr. Foster, continuing, said that it seemed to him that Mr. Young was acting on the lines of the Siemens argand burner, for by introducing a heated and heating medium the argand was practically turned into a small recuperative burner; and to warm the air supply by any means would modify to a very considerable extent the amount of light that any particular gas flame would give. He was glad that Mr. Young had brought forward the question of the character of gas flames when nitrogen was present. It was a matter which would have to be dealt with sooner or later. He felt strongly that the only way to test gas with satisfaction to both producer and consumer was to have a standard which should be independent of the material to be tested. He was glad, therefore, that Mr. Dibdin had referred to the test by atmospheric air carburetted by petroleum vapours, for such a material as that was independent of the body to be tested. Whether it could be made by special devices to yield results of a reliable and uniform character was another question. But at any rate they got rid of the initial difficulty of connecting the thing to be tested with the means of testing

it. He quite agreed with the author that certain points in connexion with the use of chimneys were worthy of more consideration than they had yet received. They were trifles, he admitted; but such trifles might make a difference of large sums of money to the gas companies. Another point which had occurred to him in listening to the paper referred to the mode of burning the candles. For instance, if they had a wick which was not perfectly straight, it seemed to him that they must have a character of flame which could not possibly be the same physically as one which was a perfect cylinder. That was not the kind of thing they got when the flame was merely a conically shaped mass. The external area of such a flame must be greater, and there must be a different character of combustion for each unit of weight of sperm burnt. He had often wondered that nobody had attempted to construct a candle with an indestructible wick. There would, of course, be nothing in it, except a flood of criticism; but it did seem to him that it should be worth somebody's while to construct something of the kind, which would be really a lamp. The material of the candle might be either sperm or paraffin, and the wick might consist of asbestos threads, glass, or any other non-combustible material, the candle being pushed up by a spring, as in carriage lamps. He had too many such foibles on hand to attempt it himself; and what was everybody's business became nobody's business. No one was interested in doing more than substitute a new standard in place of the candle. Still, with all its defects, the candle lived on; and seeing that it could be easily procured and used without much preparation, its term of life seemed likely to be still further prolonged by the experiments that Mr. Young had given them.

Mr. D. A. SUTHERLAND could confirm the results obtained by the author from trimming the wicks of his candles. With reference to the use of a paraffin candle as a standard of light, it was impossible to obtain a candle of such constant composition as to give a uniformly constant light. The German plan, therefore, must fall through, and the pentane flame become the only reliable standard. Further, in making a large number of tests per day with different lights the use of candles was very tedious. In testing oil gases of varying compositions by means of the measured flame, he had found considerable variation. He would expect that the nature of the hydrocarbons would materially affect the character of the flame obtained, and he was glad to be corroborated by Mr. Young. The class of oil usually employed in the Pintsch apparatus was of sp. gr. 0.840 to 0.850, but he would like to ask Mr. Young whether he had ever experimented with oils of a higher specific gravity than that, as the oils most suitable for enriching water-gas appeared to be of sp. gr. 0.900, or higher. He thought it would be worth his while to do so, as in the course of a few months' time London would be supplied daily with some millions of cubic feet of carburetted water-gas.

Mr. G. R. MORRISON had some experience in gas testing in Glasgow, and could say from his own knowledge that the form assumed by the wick in burning was of very great importance. He would show on the blackboard what that effect was. [Mr. Morrison here drew diagrams on the board indicating the various forms assumed by the wick of a candle in burning.] Mr. Dibdin had referred to the normal and abnormal conditions of burning, and his illustrations would indicate to those who were intimate with the subject what were the conditions desired by the managers of the gas companies. If the wick bent towards the argand, the illuminating power of the gas went down 1 to 1.5 candles; if it bent the other way, the illuminating power went up from 1.5 to 1.7 candles. He thought the position should be at right angles to the pencil of light. Another point which he considered of great importance was the number of apertures in the argand burner, and the diameter of those apertures. In Glasgow they used a No. 8 batwing burner as the standard, burning five cubic feet at five-tenths pressure. The result was that it was not a fair standard of comparison if the candles were used with the wicks pointing indiscriminately in any direction. They had the apertures at a particular angle for certain gases. If they changed the angle of the apertures, an entirely

different result was recorded—he would not say whether it was higher or lower—this depending upon the quality of the gas. He would like to know whether the author had taken that matter into account, and whether any particular size of burner and number and size of apertures was stipulated for in England.

Dr. S. RIDEAL had been under the impression before Mr. Young's paper was read that the subject of standard candles had been thrashed out. At any rate the paper, and the graphic remarks upon it had, he thought, conclusively proved that there was no such thing as a normal standard candle. A normal standard candle was now shown to be the name given to a genus of candles, including a great variety of species, and it had been further shown that the different species gave rise to many varieties, depending chiefly on their environment at the time of burning. That particular aspect of the question had not been raised on the present occasion, but those who were acquainted with the subject knew that the photometer itself had a considerable influence on the results obtained, depending upon whether it was in an enclosed or an open box. The results were affected not only by the position or bending of the wick, but by the rate of flow of the air, and by the air being heated or not heated, as Mr. Foster had pointed out with respect to the standard burner. All these things pointed clearly to the fact that a reliable standard candle did not exist, and that steps should be taken to abolish the candle as a standard of light. Mr. Dibdin's work on this subject had been well known for many years past, especially his work in connexion with the British Association Committee, which had reported some years ago in favour of altering the standard of light. His idea of doing away with coal-gas and candles as standards and substituting air carburetted with pentane had the additional advantage that they not only had a record of the results given by the test, but a means of checking whether the operator had carried out the test according to the instructions given to him. In fact, the subject had already passed the stage of discussion before scientific societies, and all that was required was to dispel the lethargy of public bodies such as the London County Council, and arouse them to take steps towards altering the present unsatisfactory state of things. The Board of Trade were already discussing the matter, and the sooner an Act of Parliament was passed or a commission of experts appointed to devise a new standard the better.

Dr. C. R. ALDER WRIGHT said that there was one point not touched upon by previous speakers, and upon which he would like to elicit a little information. What was meant by a sperm candle from the chemical point of view, or, in other words, what was sperm as employed as a standard? Was it defined as being made of material having a particular melting point? The commercial article did not seem to have a perfectly definite chemical composition. It was possible to obtain half a dozen samples of spermaceti, each one of them good in colour, specific gravity, and all the other physical conditions, but which would be found to differ considerably when tested chemically for the amount of free palmitic acid present. One might contain as much as 10 per cent. and another only one-tenth per cent. or none at all. He had a strong impression that differences of that sort might have a considerable effect on the results, by influencing the rate at which the material burned, or, if that were the same, the amount of light given out by it. He would like to ask, therefore, whether the candles had been examined from the chemical point of view as well as from the physical light-giving point of view, so as to see if it were pure cetyl palmitate present. With regard to sperm, it might not be generally known that varieties of spermaceti were sometimes sold which contained from 25 to 30 per cent., and even more, of free fatty acid. One method of purifying crude sperms consisted in treating them by a small amount of caustic alkali, one result of which was that the purified spermaceti obtained often contained a little cetylic alcohol, separated by the treatment from its compound ether, and which probably burned differently from the true compound ethers which were the normal constituents. But besides this, the residues which contained the palmitates produced as the complementary

products of the cetyl alcohol were often worked up and the free acid isolated from them, and mixed with fresh quantities of sperm. He had met with samples containing as much as 35 per cent. of free acid derived from such source. It was, however, difficult to convince people that spermaceti of that description was just as bad as that intentionally adulterated with candle stearine, *i.e.*, mixed stearic and palmitic acids derived from tallow and palm oil, &c.

A MEMBER inquired what was the range of melting point of ordinary spermaceti as used for candle-making?

Dr. WRIGHT replied that he could not say precisely from memory without referring to his notes. But he had examined side by side different samples of spermaceti, some of which contained practically no free acid, and some as much as 1 or 5 per cent., and had found little or no difference in their respective melting points, a result quite different from what one would have expected *a priori*, but probably due to the material having been pressed in each case until the required melting point was attained.

Mr. T. S. LACEY regretted that no authorities connected with the gas companies had thought it worth while to criticise a paper on so important a subject. He feared that anybody in his own position speaking on such a subject—which, however, was one that interested him greatly—ran the risk of appearing to hold a brief for the companies. He wished to state therefore that he spoke quite independently of them. Mr. Dibdin had raised the point of what was a normal candle. He thought it was only fair to regard that question from the point of view of the ordinary consumer. Such a person would take a number of candles and burn them from beginning to end, neither blowing them out nor snuffing them. They were not meant to be snuffed, and they were not snuffed by the ordinary consumer. Such were, in his opinion, normal candles, namely, candles burning from beginning to end without disturbance, and an average of the candle, or a number of them, being taken. An average of 100 or 1,000 would give them something very near the truth; but that being impossible, they took a small number of candles and got a large number of variations, some of them rather astounding. So far as Mr. Young's researches had gone, they were very interesting to him, and he must also say very surprising. It was astonishing that so much concordance could be obtained with a standard which was known to be variable in the ordinary way. But the figures showed conclusively that a candle treated by Mr. Young's method was capable of being used as a standard; whether it was a standard candle, he would not discuss them. If they looked at the table of results given, they saw that at first the results were higher, then lower results were given, and by-and-by they became normal, showing that the rate of burning was approaching the average. But those first high results should, he thought, be taken into the general average. It was unfair to reject them, since they all belonged to the general results of the candle. That the candles burnt by Mr. Young's method did give a more regular light appeared to be proved by his tests. But whether they were right in adjusting the wick or not, it was quite clear that the wick should not be snuffed. If the candles were burnt in a certain way, the more those conditions could be maintained the more likely one was to get regular results. The candle during burning changed its conditions, and if one could overcome that difficulty the results obtained might be constant; but whether they would be the same as if the candle had been left alone was another question. With regard to other standards, he did not think that anything they might say that night would be likely to settle that question. Much argument would occur in the future, as much had in the past, before they would be any nearer to getting a substitute for the candle at present used. The difficulty did not consist in getting a tolerably regular standard, but that if they adopted a standard that made his company's gas, for instance, 15 candles instead of 16½ candles, his company would certainly say that it was not a fair test, though they (the inventors) might say that it was. The problem was to determine whether the standard

really represented a certain factor of the candle or not; and until that was settled it would be impossible to substitute any other standard for the candle. The tests showing the effects of using different chimneys were very important, and the author deserved much credit for the work done in that connexion, as well as for the paper as a whole. With regard to the 2½-in. flame, there could be no doubt that such a flame under the conditions of Mr. Young's experiments gave a 14-candle light with his candles. But whether a 2½-in. flame without the gauze curtain round the bottom of the burner would represent the same amount of light was quite another question. He felt certain that by placing anything round the burner, or making any alteration in the air supply, one would make a great difference in the flame. One effect of altering the air supply would be to increase the length of the flame, and therefore less gas would be passing through the burner to produce the 2½-in. flame, and consequently less light would be obtained with the gauze than without it. But of course gas was not tested so; and he did not suppose that Mr. Young had any idea of doing so. By simply measuring the length of the flame he found a coincidence that a constant light was given; and he thought that Mr. Young was quite right, when he found that in a number of tests under certain conditions the light was constant, in regarding it not as a coincidence, but as something good enough, for his purpose, to be taken as a standard. It was convenient and workable; but to say that such a flame would give a certain illuminating power under other conditions would be more than they had a right to assume.

Mr. S. H. JOHNSON said that, with reference to the proposed pentane standard, it appeared to be very important, bearing in mind Dr. Wright's remarks, that a body of absolutely fixed chemical constitution should be used as a standard of light. In that respect the pentane standard had a great advantage over the candle. But it must be looked at from another standpoint. The pentane standard depended for its accuracy not only on the purity or fixed composition of the pentane, but also on the fixed composition of the gas produced by the mixture of air with the pentane vapour. That would, however, vary with several conditions. The first and most important of these was that the tension of the vapour of pentane would vary with the temperature. He would, therefore, like to ask Mr. Dibdin whether that factor had been taken into account. Other causes of variation would be alterations of atmospheric pressure and degree of moisture. It was necessary that these variations should be taken into account or eliminated.

Mr. DIBDIN said that he would reply to Mr. Johnson at once. There was a certain amount of confusion in the minds of both Dr. Rideal and the last speaker, which had led them to mix up the pentane one-candle standard of Mr. Harcourt with the pentane argand introduced by himself. The two things were different. Mr. Harcourt's method was to take a measured volume of atmospheric air, corrected for temperature and pressure, and a measured volume of liquid pentane, also corrected, and he incorporated them so as to get a perfect mixture of the two, every possible precaution being taken in the operation. That mixture was burnt in a specified burner at a certain rate, and that constituted Harcourt's one-candle pentane standard, which was proposed as the standard of light. Many people, however, objected to it, as being too delicate for the ordinary examiner. Something more handy was wanted, and it occurred to him that it would be desirable to try the effect of passing atmospheric air over a body of the pentane, paying no regard to the volume of the air, the quantity of pentane, or to any external circumstances other than the height of the flame when burnt in a special argand burner with the top of the flame cut off by a screen, the whole of the blue portion being included in the standard. He had found that the results were very constant. He had filled his carburettor first with ice and cold water, and got the same result. There was a reduction of the flow, and he had to increase the pressure; but the standard of light was exactly the same. He had then taken away the ice and cold water, and replaced them by water at 100°, with the result that the pentane almost boiled, and an enormous rush of gas occurred. He had to

check the flow by turning down the flame to 3 in. in height, when the volume of light was exactly the same as with the ice and cold water. That disposed of the question of temperature. With regard to pressure, there must, of course, be sufficient to give a 3-in. flame. It seemed almost incredible that so constant a light should be got under such extreme conditions as those he had mentioned, and at first it puzzled him. But he also found that whether the carburetted air was cold or warm, he could alter the height of the flame from $2\frac{1}{2}$ in. to 4 in., and yet the amount of light passing under the screen would remain constant. If the flame was over 4 in. the colour was altered. They therefore had a test which was as elastic as one could wish, and yet by using the amount of light which passed under the screen they had a constant standard. Then he had noticed that as the quality of the gas or the degree of temperature of the carburettor altered, a change occurred in the relative volumes of the white and blue flames, and as it was evident that these variations exactly compensated one another, the result being that he always got the same amount of light (10 candles) passing under the screen. The arrangement might, however, be modified to give the light of 16 candles, or any other desired quantity.

MR. FOSTER remarked that the screen was, in fact, an opaque body cutting off the top of the flame, and that Mr. Dibdin used a flame of any height, but took only a definite portion of it which was always constant in height.

MR. JONXSON said that that was what he was about to ask: how Mr. Dibdin selected the portion he used as a standard? He supposed that he used the same fixed screen equally for all his experiments.

MR. DIBDIN said that was so, the position of the screen being determined by experiment, using the pentane one-candle flame as a standard of reference.

MR. W. C. YOUNG, in reply, said that he did not agree with Mr. Dibdin in his view that it would be necessary to alter the law if his suggestions were to be carried out. The present law provided for the issue of instructions by the Gas Referees to the examiners as to the mode of testing gas, and they had already ordered that the candles should be used in a particular manner. He did not see why they should not go further and order that what he had suggested should be done. That would be quite sufficient, and it would be unnecessary to go to Parliament for an alteration of the law. Mr. Dibdin had also said that the gas companies expected the examiners to use the candles so as to get high results, while the examiners preferred to use them so as to get low results. His experience, however, was that if one did his work carefully and impartially the companies made no objection to what one did. Nearly the whole of the experiments in Table VII. had been made in the presence of the officials of one of the companies, and they had taken no exception to the results, though they were perfectly well aware that all his testing had been made in that manner for years. And the same remark applied to gas managers all over the country. He said that because he thought it was only fair to the gas companies to do so. With regard to the value of the $2\frac{1}{2}$ -in. flame, that length was the whole flame, and not $2\frac{1}{2}$ in. screened off from a longer flame. He was rather surprised to hear Mr. Dibdin say that the portion which he screened off from his flame was invariable in lighting power, no matter what the total length of the flame was.

MR. DIBDIN, interposing, said that he used a special burner, not the standard argand.

MR. YOUNG said that it might be different in that case. With an ordinary burner, $2\frac{1}{2}$ in. screened off from a 3-in. flame would give a light of 15 candles power. It was not possible without some such apparatus as the gauze curtain referred to in his paper to say whether the length of a flame was $2\frac{1}{2}$ or $2\frac{3}{4}$ in., and the effect of the difference would be very important. Mr. Dibdin had also raised the question of the value of the Parliamentary candle. Table III. showed the value of that candle, made with sperm containing 5 per cent. of wax, as supplied to the testing stations: and the average showed that in the case of No. 1 the flame

equalled 14.65, &c. That was taking the whole candle and using it as many times as possible under the prescribed conditions of working. A comparison of Tables III. and VI. showed the difference between using the whole candle and working as he proposed, roughly, about half a candle. The companies were liable under the existing law to have all the tests taken with candles that had been used several times, in which case they had the conditions which he said should always obtain. It was only because they had to break the wick in order to halve the candle, and thus made it rough, that the flame did not give its full power at first. But as soon as the wick became properly bent, then there was a definite amount of light for the sperm burnt. That was shown by the experiments, and was a condition which ought to be imposed on the companies, and one to which he did not think they would object. Mr. Dibdin had objected that lighting and blowing out the candles three times was tampering with them. But that was done with every candle used, for one never burnt it right out, using it for one test only. The Gas Referees required that a different candle should be used for each test, and as the examiner employed the candles till they were used up, the result was that even in the ordinary way of working a candle was lit and blown out seven or eight times. But what he objected to was taking the tests obtained during the first two or three times the candle was lighted; they were not correct, and ought to be rejected. He had no doubt that Mr. Dibdin's standard burner, if used by a careful workman, would give constant results. His own experiments, with a $2\frac{1}{2}$ -in. flame of coal-gas had proved that, given the possibility of accurately measuring the flame, and a properly constructed apparatus to start with, the light coming under the screen would be of constant value. But there was the difficulty that they must have a standard that could be taken all over the country, and not confined to the elaborately fitted stations of the Metropolis. They wanted such a standard that a man who had to use it officially in the provinces only six or seven times a year, could be sure of finding it fit to use at any time. Supposing a pentane standard were adopted: A gas examiner visiting a country gas works would want to use his own carefully verified pentane, but the manager would want him to use his (the manager's) pentane, to which he would object; and there would be a difficulty at once. That was the objection to all such standards. But candles could be carried in the pocket, and were so obviously standard candles, that no manager ever thought of objecting to them. Moreover, they could be left at the works for testing by the officials if they were so disposed. Mr. Foster had objected to his curtain being used for testing purposes. But he had not suggested in the paper that it should be. It was employed only for the purposes of the paper; and he found that with it a $2\frac{1}{2}$ -in. flame was equal to 14.18 candles. He had made many experiments with flames of various length, and found that the curtain made no difference whatever to the light. A test taken with the gauze curtain on, which enabled him to read off the exact $2\frac{1}{2}$ in., did not differ from another taken after the curtain was removed, more than two-tenths of a candle in the result. Another point that had been raised had not, he thought, been made enough of. That was the question of the dimensions of the standard test burner. The Referees went into minute particulars with reference to the dimensions of the holes; but the examiners were not provided with the means of ascertaining whether the dimensions were correct or not. They were provided with standard test burners, but they never tested them, in fact one part could not be tested without cutting the thing to pieces. He very much doubted whether any two were alike, for he knew that the burners in two different stations differed in the pressure required to pass 5 ft. from 2.5 tenths to 4.2 tenths. Those two could not be of the same dimensions. If they were to be so particular about their standard of light, they should first see that the instruments in which the gas was burnt were of exactly the same dimensions in every case.

MR. DIBDIN remarked that to his own knowledge the standard burners used in London were all most carefully measured by the Board of Trade, and were not sent out unless they passed their measures.

Mr. YOUNG replied that he did not know whether that was the case with all the burners. One of those he had referred to was in a provincial testing station, and the other in London. Of course they might agree while the burners were new. But they remained in the stations without change for years, and it was not reasonable to suppose that after, say, eight years, they were of the same dimensions as when newly made.

Mr. DUNN said that so far as the district of the London County Council was concerned, it was his duty to compare the burners from time to time with the standard. He did so, and he had never found any alteration of the lighting power due to the burner being used even for eight years.

Mr. YOUNG, continuing, said that Mr. Foster had referred to the shape of the candle flame. If he would look at the photographs which were to be exhibited after the meeting he would see that the shape of the luminous part of the flame was essentially different in one case from what it was in the other. In the case of the candle burnt as he recommended, the base of the luminous flame was almost level, while in the other instance it extended lower down on one side of the cone, and the flame was less conical in the latter case than when his method was followed. The idea of an incombustible wick and a spring under the candle had been suggested many years ago, and was tried by Dr. Lathely, who rejected it because he found that he could not keep his candles from guttering.

Mr. FOSTER said that he had intended to convey the idea of a candle made without a wick, and an incombustible wick pushed up through it.

Mr. YOUNG, continuing, said that in reply to Mr. Sutherland's question he could only say that Pintsch's oil-gas was the only one he had tested. But he had tested coal-gas that had been enriched by light oils, and also water-gas carburized by both light and heavy oils, and the difference in the luminosity of the respective flames was distinct, and was referred to in the paper. The Pintsch's oil-gas and coal-gas enriched by light hydrocarbons gave the same illuminating power, using a $2\frac{1}{2}$ -in. flame, as did coal-gas alone, but the rate of consumption was very much less in the case of water-gas enriched by hydrocarbons, the illuminating power of a $2\frac{1}{2}$ -in. flame went up to 18 candles; and the flame enriched by petroleum instead of coal was increased from 14 to 15 candles. Mr. Morrison had referred to the shape of the wick. That matter had been dealt with in 1876, when its effects were clearly pointed out in the "Gas Journal." The Gas Referees at length saw that there was something in it, and in their instructions to the examiners they made such arrangements as to practically prevent any interference with the relative position of the wicks one to the other. Dr. Rideal seemed to be of opinion that all the work of gas examining was scientific, or should be so. His experience, however, was that it was really a matter of commercial valuing rather than of scientific experimenting. What they really wanted was a reliable means of testing the gas, which should not be too scientific for an average gas manager to comprehend and use himself; and that they had, he thought, in the candle. He feared that the average manager of a small gas works would not be able to work with such a standard as Mr. Harcourt had proposed. In answer to Dr. Wright, he had not made analyses of the sperm in the candles, and had no idea of its composition. He had taken them indiscriminately from different sources, had tried them as shown, and had found them to agree fairly well one with another. They were all supposed to be standard sperm candles of six to the pound, as required by the Act. Mr. Lacey (who, he regretted to say, was the only speaker on behalf of the gas companies) seemed to think that a candle could only give normal results when burnt, and kept burning, from beginning to end; and, further, that a candle should never be snuffed. His memory, however, took him back to a time when gas was not so general as now, and in those times a pair of snuffers was an essential part of the furniture of a sitting-room, though they were now only seen as curiosities.

Mr. LACEY: They were not used with sperm candles.

Mr. YOUNG: Mr. Lacey had also raised the question as to whether, in fixing a new standard, an average should be taken right through the life of the candle, or whether it should be taken as he (Mr. Young) had suggested. That question could only be settled by discussion between the authorities and the companies; and as the authorities had practically given the companies the benefit of half a candle in the last Act, the latter might now be gracious and give up a half in the case of any new standard, and he thought it very likely that they would.

Meeting held on Monday, 16th February 1891.

MR. WM. CROWDER IN THE CHAIR.

INCANDESCENT GAS LIGHTING,

BY W. MACKEAN, F.R.S.

THERE is no doubt that the question of gas lighting is at present attracting a good deal of attention on account of the progress that is being made with the electric light, and as I find but little record in the Society's Journal regarding gas lighting by incandescence, I think the subject one of sufficient interest to bring before the members of this Society.

The pure atmosphere, the steady brilliant light maintained where electric light is employed are so much in advance of the unpleasant atmosphere and unsteady flame resulting from the use of coal-gas, that it is not surprising electric light is so much more appreciated, but when we come, however, to consider the cost of electric light compared with that of coal-gas, the high price of the former at once gives coal-gas such an advantage as to almost defy competition for ordinary household illumination.

Nevertheless a demand has sprung up to obtain a higher standard of illumination from coal-gas which shall as far as possible possess the many advantages of electric light in point of brilliancy and steadiness, and maintain a comparatively cool atmosphere.

The production of light for illuminating purposes by the incandescence of refractory materials, such as platinum and iridium, or the oxides of zirconium, magnesium, &c., is not entirely new, but their adoption for ordinary household illuminating purposes has only recently been attempted with any degree of success. Several forms of lighting by incandescence have already been brought before the public, among the more important being the Welsbach, Chumond, Lewis, and Sellen.

I desire, however, to refer more particularly to the Welsbach system, as during the past three years I have had special experience in the working of this system in my capacity as chemist to the company.

In this, the Welsbach system of incandescent gas lighting, a hood or "mantle" composed of the oxides of the rare earths, such as zirconia, thorina, yttria, &c. is employed which is prepared as follows:—

A cotton thread is knitted into a cylindrical shape in network form, washed first in dilute ammonia, then in water containing a little hydrochloric acid, finally in distilled water, and dried. The knitting is then cut up into suitable lengths, saturated in a solution of the lighting fluid, composed of the nitrates of zirconium, lanthanum, thorium and cerium, and dried on glass rods at a temperature of 90° F.

A fine platinum wire is then passed through a double thickness of the net, forming the top, by which means the mantle is attached to a stout steel wire or support. The mantle is then drawn into shape by being pulled over a model of the desired form, and the flame of a Bunsen burner afterwards applied to the upper portion of the mantle, which

burns slowly downwards, and shrinking considerably in length, the cotton being entirely consumed, leaves only a fine network of the oxides, zirconia, thorina, &c., which on being placed over the flame of a Bunsen burner at once becomes incandescient, emitting a bright steady light.

By altering the nature and composition of the fluid employed the light obtained can be varied from an intense white light to a golden yellow or greenish colour, which differ to a certain extent in their diffusive power.

The following compositions will give a fair idea of the changes of light as regards colour :—

WHITE LIGHT.

I.	Per Cent.
Zirconium oxide	40
Lanthanum oxide.....	40
Thorium oxide	20

II.	
Zirconium oxide	40
Lanthanum oxide.....	60

III.	
Yttrium oxide	20
Thorium oxide	80

The above compositions may be considerably altered without affecting the colour of the light.

YELLOW LIGHT.

I.	Per Cent.
Lanthanum oxide.....	40
Thorium oxide	28
Zirconium oxide	30
Cerium oxide	2

II.	
Zirconium oxide	47
Lanthanum oxide.....	50
Cerium oxide.....	3

ORANGE LIGHT.

I.	Per Cent.
Lanthanum oxide.....	49
Thorium oxide	30
Zirconium oxide	27
Didymium oxide.....	3

II.	
Lanthanum oxide.....	50
Thorium oxide.....	40
Niobrium oxide.....	10

GREEN LIGHT.

	Per Cent.
Thorium oxide.....	50
Lanthanum oxide.....	20
Erbium oxide.....	30

Many other oxides may be employed in the compositions, but the presence of some, such as alumina and magnesia, are very detrimental to the duration of the illuminating power.

Of the many substances which may be employed, cerium oxide is the most satisfactory for the yellow lights, when added in small quantities. Didymium oxide has the effect of causing a rapid diminution in the light, unless a high temperature can be maintained.

I find the most effective as to duration of light being composed of—

Zirconium oxide,
Lanthanum oxide,
Thorium oxide,
Cerium oxide.

to which a small quantity of yttrium oxide may also be added; mantles made from the above composition lasting from 800 to 1,000 hours.

The duration of the illuminating power varies considerably according to the nature of the fluid employed, a curious fact being that the diminution is very gradual as a rule after 500 hours burning, and the light is then much whiter in colour than when first used.

Table I. on p. 198 shows the loss in the illuminating power of mantles during 1,000 hours.

The presence of an excess of cerium is shown in Table II., p. 198.

Table II. also shows the illuminating power remains more constant when 1 per cent. cerium oxide is added to the fluid, but the colour of the light is nearly red and unsuitable for ordinary lighting purposes. The temperature of the Bunsen flame being insufficient to heat the cerium oxide to incandescence.

Mantles which give a light of a slightly yellow tint give a much higher illuminating power than those of a pure white light and last much longer, as the following table will show :—

Gas.	Original.		500 Hours.	1,000 Hours.	Colour.
	Pressure.	Candle-power.			
	Inch.				
2'5	1'0	17'6	5'4	4'3	White.
2'5	1'0	16'8	5'6	4'5	White.
2'5	1'0	25'6	18'0	13'7	Yellow.
2'5	1'0	27'2	17'6	13'0	Yellow.

The illuminating power of the different oxides vary considerably both in colour and intensity, and differ to a large degree in the properties during the manufacture of the mantle.

The oxides of thorium, zirconium, yttrium, and aluminum when cold are rather brittle, but when brought to incandescence they become very flexible and easy to work.

Lanthanum, cerium, didymium, and magnesium oxides on the other hand are very brittle, even when incandescence, and are more difficult to work, but a mixture of the oxides, provided the lanthanum does not exceed 50 per cent., are very flexible when brought to incandescence.

The following table (which I hope to be able to make more complete) shows the illuminating power obtained from the pure oxides and the colour of the light :—

	Candle-power.	Gas.	Pressure.	Colour of Light.
Lanthanum oxide	22'5	3'0	Inch. 1'0	White.
Zirconium oxide.	12'2	3'0	1'0	White.
Thorium oxide	25'0	3'0	1'0	Bluish white.
Yttrium oxide...	19'8	3'0	1'0	Yellowish white.
Cerium oxide....	4'0	3'0	1'0	Nearly red.

The highest illuminating power I have been able to obtain from a mantle of the ordinary size, is made from a mixture of yttrium and thorium oxides.

	Per Cent.
Thorium oxide	60
Yttrium oxide	30

A mantle of the above composition giving an illuminating power of 40 candles with 3 cubic feet of gas at 1'0-in. pressure. The duration of the light I have not yet fully determined.

TABLE II.
TABLE SHOWING PRESENCE OF EXCESS OF CERIUM OXIDE IN LIGHTING FLUID.

Gas, Cubic Feet per Hour.	Pres- sure.	Original Candle- power.	After 100 Hours.	200.	300.	400.	500.	600.	700.	800.	900.	1,000.	Difference in Candle- power.	Percentage Loss in Light.	Remarks.
2.5	1.0	25.0	22.2	21.0	20.4	19.0	19.0	19.0	18.7	16.5	15.0	14.2	10.8	43.2	Ordinary lighting fluid containing .25 per cent. cerium oxide.
2.5	1.0	18.0	18.0	17.2	16.5	15.0	14.5	13.6	13.0	12.4	12.0	11.4	6.6	36.6	Above fluid contain- ing .75 per cent. cerium oxide.
2.5	1.0	17.8	17.7	15.8	15.2	14.0	14.0	13.0	13.0	13.0	13.0	12.2	5.6	31.4	
2.5	1.0	13.5	13.5	13.5	15.0	13.0	13.0	13.0	13.0	13.0	13.0	11.8	1.7	12.6	Above (ordinary) fluid containing 1.0 per cent. cerium oxide.
2.5	1.0	13.2	13.2	13.2	12.8	12.0	12.0	12.0	12.0	12.0	10.8	9.5	3.7	28.0	

To obtain a good illuminating power it is absolutely necessary to have the salts as free from impurities as possible, and special care has to be taken to get rid of the last trace of iron which affects the illuminating power to a very large extent, the amount of iron usually present in the fluid being from 0.001 to 0.003 per cent.

IRON PRESENT IN OXIDES.

	Fe.	Fe ₂ O ₃ .
Lanthanum oxide001	.0014
Lanthanum ammonium trade crystals..	None.	None.
Thorium oxide005	.0071
Zirconium oxide007	.010
Cerium oxide003	.0043
Dysodium oxide003	.0043

The above estimations were made in the salts (nitrate) and calculated to the oxides.

Perfect combustion of the gas should also be carefully obtained as, if too much gas is used causing the flame to smoke, the illuminating power is considerably reduced, and a deposit of carbon takes place inside the mantle which often increases to such an extent that the mantle is broken and thereby destroyed.

It is necessary that the flame of the Bunsen burner should be inside the mantle, as the presence of air or oxygen is

necessary to obtain a good result, as the oxide only gives illuminating power in the oxidising flame of the Bunsen. This is accomplished by means of the chimney, the best form of which is contracted about two inches from the base, which forces the air on to the mantle and keeps the flame in the desired form.

The chimney usually employed is 9 in. in length, 2 in. diameter at the base, and 1½ in. diameter at the top. The illuminating power differs according to the height of the chimney employed.

Gas.	Pressure.	Chimney.	Illuminating Power.
		Inch.	Candles.

It was my intention this evening to have gone into the question of incandescent lighting by means of water-gas, but as the experiments have not yet been completed, I have decided to withhold them till completed, and hope to be able to lay them before the Society at a future date.

In the Clamond system of incandescent gas lighting a basket or hood of magnesia and zirconia is employed,

which is heated to incandescence by an atmospheric burner of peculiar construction, whereby the air and gas are heated before combustion takes place. The hood is prepared by mixing pure magnesia with the solution of magnesium acetate and forcing the mixture through a suitable die, from which it issues in a continuous thread, and is wound into shape on a mandrel. The illuminating power obtained with this system is when at its best, 5 candles per cubic feet, the chief drawback being the short life of the hood, which burns out in about 100 hours.

A number of systems have been shown whereby illuminating power is obtained from the metals platinum and iridium, among them being the Lewis and Sellon.

In the Lewis system a small hood of platinum or alloy of platinum and iridium is used, which is brought to incandescence by the Bunsen burner, perfected by Lewis, in which the air is admitted under pressure, this being a great drawback to its application for domestic purposes. The hood is brought to a high state of incandescence and emits an illuminating power of 200 candles, when consuming about 40 cubic feet of gas per hour, being equal to 5 candles per cubic foot. It is a curious fact that when the hood is incandescent the temperature is so great that it may be exposed to rain without being in any way affected. It is well suited for outside purposes or large buildings.

In the Sellon system a cone of metal gauze is employed heated with a Bunsen burner of the same form as that employed with the Lewis. Another modification is that of a downward light, obtained by suspending a small piece of the refractory material (platinum gauze) between two diaphragms of asbestos, the gas and air are allowed to mix in a small glass bowl, afterwards burning at the top of the gauze which is immediately brought to a high state of incandescence, no flame being perceptible, showing perfect combustion is obtained. In another modification the air and gas are carried in a small metal cylinder to the top of the outlet of the gases, and are heated in their passage downward before combustion takes place, the illuminating power being about 5 candles per cubic foot.

The attempts hitherto made with carburetted water-gas have not been so successful as to meet with their general adoption. The system of Fahnehjelm, a Swedish chemist, is being extensively employed. This consists in attaching small pencils of magnesia or a mixture of magnesia and zirconia to a small frame in the form of a comb which is suspended over the flame of a water-gas burner and is immediately brought to a high state of incandescence. The pencils are prepared much in the same way as the Clamond hood or mantle. This system gives a very beautiful intense white light and is not at all expensive, one drawback being the duration of the magnesia cone, which lasts only from about 50 to 100 hours, but this is considerably increased when magnesia and zirconia are employed. The magnesia cone costs only about 3d., is easily replaced, and the cost of lighting by this system is much less than that of ordinary gas, and the illuminating power considerably greater.

Before any system of incandescent gas lighting can be considered a success, so far as the adoption for ordinary use is concerned, there are many difficulties to be overcome, among them being as follows:—

1. Existing fittings should not be interfered with, except so far as the burner is concerned.
2. The system ought to give a better and steadier light than the ordinary gas flame.
3. No separate service of service pipes must be required, and the arrangement of the system must be as simple as that required for ordinary gas. There should be little or no liability of breakage or derangement.
4. The duration of the lighting medium must be so great that the cost of renewals should be inappreciable.
5. The consumption of gas must not be increased, but on the contrary a very marked saving in the consumption, or its equivalent in increased light, must be secured.
6. The combustion of gas burnt must be more perfect than the ordinary gas burner, in order to reduce the objectionable and destructive effects of gas consumed in dwellings.

7. The atmosphere must be comparatively cool, and the light must not greatly deteriorate by the use of the illuminating medium.

As regards the above-named systems shown, notably Clamond, Welsbach, and Sellon, the existing fittings are not interfered with, but at the same time a good pressure of gas (not under 1 in. pressure) is essential to obtain satisfactory results. The systems mentioned give a better and steadier light than the ordinary gas flame, being an inducement towards their employment. So far, none of the systems fulfil the conditions of ordinary gas as regards the simple arrangement required, all of them requiring more care and attention than the ordinary gas burner. A higher candle power per cubic foot is obtained, but at the same time with all the systems there is a gradual decrease in the illuminating power, and renewals of the illuminating medium are necessary to obtain the maximum amount of light. In incandescent gas lighting, the combustion of gas being perfect, the destructive effect on ceilings and paintings is much less than with the ordinary gas burners. That the illuminating medium will remain constant seems impossible so far, as with gas we have a continually renewed service for illumination, while the resistance offered by the illuminating medium employed in incandescent gas lighting to the ignited gas, and air drawn into the chimney, very soon causes an alteration in the lighting power, but which after a time remains fairly constant.

I have no doubt that considerable progress will be made with regard to the systems at present employed, and in the future, incandescent gas lighting, provided the present difficulties are overcome, will be a serious competitor to electric light for ordinary domestic use or general illumination.

DISCUSSION.

Mr. F. SCUDDER said that he had hoped to have been able to bring before the meeting some improvements in the application of water-gas to illuminating purposes, but unfortunately the experiments were not in a sufficiently advanced state to enable him to do so. In 1888, Mr. Wilson had read a paper before the Society on the subject of the production and application of water-gas, and the Fahnehjelm comb was introduced and explained on that occasion. His only excuse therefore for bringing it forward again now was that it had been improved in the meantime. He had had occasion to visit America last autumn in connexion with his investigation of the production of water-gas, and while there he found that better results were being got with the comb than in England. The comb hitherto used here came from Essen. It gave a pure white light, and was stated by Mr. Wilson to have an illuminating power of 3.5 candles per cubic foot of gas. The American comb, however, gave a five candle power for the same amount of gas. On investigating the matter, he found that the American comb underwent a course of treatment after manufacture. The ordinary comb consisted of a number of needles of pure magnesia, which gave an intense white light. The American combs were dipped into a solution of chromate of potash, allowed to dry, and then ignited. This treatment gave them a yellow light, which was found to have a higher illuminating power and a greater degree of diffusion. Mr. Mackean had obtained a similar result with the Welsbach burner by the addition of cerium. In the paper to which he had referred, Mr. Wilson had made the following statement: "Looking at the efficiency of these various systems relatively with ordinary gas lights, and taking them all simply as machines for converting heat into light, which appears to be a useful test, the following table has been prepared to show approximately the number of heat units required per hour to produce one-candle power by various ordinary and incandescent arrangements. From this it at once becomes clear that the incandescent system is essentially the one for producing the most light with the least heat." (See Table, Vol. VII. p. 23.) The German comb deteriorated to such an extent that if burnt with water-gas at the rate of five cubic feet per hour it would only last 100 hours, losing 25 per cent. of its illuminating power during that period, whereas the American comb, in which the needles were shorter, would last 150 hours under the same conditions. In testing the illuminating

power of the new Faldachjelm comb, he had also tried a Welsbach mantle with water-gas. It was necessary to alter the usual arrangements of the Welsbach burner, on account of the air required for water-gas being about only one-half of that required for ordinary coal-gas; but he had found that for each cubic foot of water-gas consumed he obtained an illuminating power equal to 7 candles. He had seen a specially designed Welsbach burner for natural gas in use on a large scale in Pittsburgh and Philadelphia which gave an illuminating power for each cubic foot of gas consumed equal to 3.5 candles. There was no doubt a large field open for incandescent lighting in this country, and the use of water-gas in conjunction with such a system would be of immense value.

MR. BERNARD DYER felt that he must plead guilty to very great ignorance of what were generally known as the "rare" metals; indeed, until the Welsbach Company had introduced their lights a few years ago, he had been under the impression that many of the metals whose oxides were now employed in the manufacture of their mantles were not only not much known, but naturally rare in occurrence. He did not know whether his ignorance was shared by many other chemists present, but if so it would be of interest if Mr. Mackean would give some further information as to the sources of some of those oxides and the methods of obtaining them in commercial quantities. He would also be glad of further information respecting the chemical changes in the mantles to which the deterioration of the light might be due. He was interested in that aspect of the question, because he had tried the light some years ago in his laboratory, and found that, although it was satisfactory at first, in about a fortnight the power rapidly diminished, and in three weeks the mantle was useless. He thought that that must be due to the effect of the chemical vapours produced in his laboratory, for lights which had been started at the same time in his private house showed no such deterioration. He had had Welsbach lights burning in his drawing-room constantly for three years without renewal, and one of them which he returned intact to the company at the end of that time still possessed a high illuminating power. He had found the light a very comfortable one to read by; and after constant use for three years in his rooms there was a remarkable absence of that dirt on the ceilings which was the usual result of employing the ordinary gas burners.

MR. W. F. ANDERSON said that, it having been stated that it was essential that the mantle should be kept in the oxidising flame, and that chemical changes took place in the mantle which caused a deterioration of the lighting power, he would like to ask whether the oxides might not in time be reduced to the metallic condition, in consequence of the mantle being subjected to the action of the reducing flame instead of the oxidising flame. He would also be glad to know whether any experiments had been made in connexion with the photometric power of the incandescent light.

MR. A. H. ALLEN said that the same idea had occurred to him as to Mr. Dyer, namely that it would be useful to have a short account of how these rare earths, which used to be regarded as nuisances to the ordinary chemist and of interest only to the very patient scientific investigator, were now obtained. Mr. Dyer having spoken of the return of a mantle to the manufacturers after three years' use, he supposed that even after that time it had some value as "old rare metal." He would like to know whether the rare oxides employed for the Welsbach mantles, after being subjected to a white heat for so long a time, acquired an insoluble condition, similar to that of highly ignited alumina. If not, it would be easy to redissolve them by means of nitric acid, and hence recover them in a condition ready for use. He should also like the author to give them an idea of the method employed in separating these rare earths in actual practice. Such points were of considerable scientific interest, and if it were not inconvenient to the manufacturers, he hoped that some further information would be given respecting them.

MR. BRINKLEY inquired whether the oxide of vanadium had been used.

MR. MACKEAN replied that he had tried it, and had found it to give a yellow light, and to be too fragile.

MR. BRINKLEY: And uranium?

MR. MACKEAN said that he had tried that also, and rejected it because of its low diffusive power and yellow light.

MR. D. A. SUTHERLAND thought that the Society was indebted to Mr. Mackean for a very valuable paper on a subject which was but imperfectly understood, though it had been before the public for some years. Mr. Mackean had been altogether too modest in speaking of the difficulties he had had to contend with in separating the earths referred to, difficulties out of which he had come most satisfactorily. With regard to Mr. Allen's remark as to the value of old returned mantles, from his (Mr. Sutherland's) experience during a joint use of the same laboratory for the past six months, he would ask to be allowed to forestall Mr. Mackean, and state that by treatment the oxides could be recovered, and further, that Mr. Mackean had been able to deal successfully with old mantles sent as unutilisable from Germany, and had thus saved money to his company. There had been difficulties, due to the impurities which the mantles contained, but those difficulties had been overcome. With reference to the illuminating power obtained, there was one point which seemed to him to be worthy of more attention than it received, namely, the usefulness of the incandescent gas light for titration purposes. He had been very successful with it in that way, and had no doubt that by means of a Welsbach burner attached to a flexible tube, one would be able to work as well in the heavy fogs of London as one could in summer daylight. They could not all afford electric light, and therefore it was as well that the members generally should know that. Care was to be taken, however, to get a white light mantle, such as that with zirconium oxide and yttrium oxide. He was much interested in the relative diffusive power of the light from the various oxides under varying conditions, and regretted, therefore, that Mr. Mackean had not been able to give the results of his water-gas experiments. He might allude, however, to one point of great interest. It might naturally be expected that incandescent lighting being due to certain bodies being raised to a high heat, the higher the heat the better the incandescence would be. And it had proved so generally in actual practice. But some of the oxides gave a better light when water-gas was used instead of coal-gas; and it was quite possible that still better results would be got by using pure oxygen instead of air in the burner. Mr. Mackean had brought the method to a high pitch of perfection, many of the processes being his own patents, and their thanks were due to him not only for that, but for the frank manner in which he had treated the subject.

MR. G. R. MORRISON could confirm the results given by Mr. Mackean with regard to the illuminating power of the Welsbach mantles. He had had considerable experience of them, and had obtained a power of 28 to 29 candles per 2½ feet of gas consumed. That was with ordinary Scotch gas; but in some of the outlying districts of Scotland he had obtained similar results with a consumption of only 1½ cubic feet. There was some difficulty in using a gas of such high power, for he had found by experience that the viscosity of the gas being so heavy, the air and gas did not mix properly in the Bunsen burner, the result being that the combustion was imperfect, and the mantle was carbonised, just as Mr. Mackean had described. He could also confirm Mr. Sutherland's remarks as to the usefulness of the burner for titration purposes. He had found great advantage from it in that respect, and also in sugar analyses. The illuminating power of the mantles did, in some instances, depreciate to an enormous extent, and in an unaccountable manner. His own opinion had been that the high illuminating power was due to cerium; but he now found himself mistaken, as the author had stated that cerium itself gave only a four-candle power, and that it could only be used in limited proportions. His experience was that the red lights gave the highest power and lasted the longest, and that the white lights gave a low power, and depreciated rapidly. In some instances he had used yellow mantles for 2,000 hours,

and at the termination of that time they gave an illuminating power of 18 candles. On the other hand, he had had white mantles in Scotland, which gave an illuminating power of 21 to 22 candles, and after about 2 weeks burning, the power had gone down to 12 or 14 candles. He had not been able to quite make out from the paper what Mr. Mackean regarded as the standard oxide, that which gave not only illuminating power but stability to the mantles.

Mr. W. MACKEAN, in reply, said that one of the sources from which the oxides employed were obtained, was monazite. From it was got thorium, lanthanum, cerium, and didymium, but it was a complicated ore and difficult to deal with. Orthite was another source, from which cerium and didymium was obtained, this mineral costing about 1s. per kilo. Zircon, from which zirconia is obtained, was quoted some time ago at 7s. 6d. per oz., but could now be bought in quantity at about 2s. per lb. Thorite, the source from which thorium oxide was extracted, was most difficult to obtain, and the most expensive. The first supplies cost about a guinea an ounce for 60 per cent. ore, but the price was now considerably reduced, the quality averaging about 50 per cent. thorium oxide. Thorite also contained about 10 per cent. uranium oxide and 15 per cent. silica (a specimen of which was shown, as well as the mineral gadolinite from which yttrium oxide is extracted). Most of the minerals were said to come from Norway, but they had, with the exception of thorite, been found in large quantities in America. He hoped to give full analyses of the various minerals from which the oxides were derived in a future paper, and at the same time to bring before the Society some very remarkable properties possessed by the salts of the metals in question. In the extraction of the oxides, thorite for instance, was finely powdered and dissolved in hydrochloric acid with which it forms a stiff gelatinous mass, the silica passing into solution which is evaporated to dryness to render the silica insoluble. Hydrochloric acid was then added, and the chloride solution separated from silica, &c. Sulphide of sodium was added to separate lead, &c., after which hyposulphite of soda was added to the dilute solution to precipitate all the thorium as the hyposulphite; most of the impurities passing into solution. Afterwards, if necessary, the cerium, &c., were separated by bringing down first of all with ammonium oxalate from the solution of the chloride. The hyposulphite was dissolved in hydrochloric acid and then further precipitated as a hyposulphite for the second or third time. Finally, the thorium was brought down from the solution of the pure chloride with ammonia, thus getting a hydrate from which any of the other salts could be obtained. Zircon could be treated in the same way if first fused with bisulphate of soda or caustic soda, and afterwards evaporated to dryness, the chemical reactions being much the same as in the case of thorium. Cerium was prepared from cerite, but, with the exception of zirconia and thorina, all the minerals he had mentioned contained it as well as didymium. With the exception of zirconia, most of the minerals being hydrated silicates, were very soluble in hydrochloric acid unless they were first heated, in which case they became quite insoluble, excepting in boiling sulphuric acid. He had a process for separating the salts from old and broken mantles, which he would describe later on. The prices of the oxides varied very much, the lanthanum oxide being very expensive, as the ore contained only about 20 per cent. of the oxide, and it was difficult to get rid of the cerium and didymium. The oxide of zirconium only became insoluble in the ordinary acids after being heated to a very high temperature; the others were all soluble in sulphuric acid, even after burning in a Bunsen flame for 3,000 hours. He had burned some of them (the mantles) continuously for over 12 months.

The diminution in the illuminating power was partly owing to a change in the composition of the mantle. He had started with a mantle containing 40 per cent. of lanthanum, 30 per cent. of zirconium, and smaller proportions of yttrium and cerium oxides, and after burning 1,000 hours the lanthanum oxide had gone down to 30 per cent. As lanthanum was one of the salts which give diffusion, the diminution of the illuminating power appeared to be due to the loss of that salt, caused by friction at the

point where the air was drawn on to the flame at its hottest part. A further proof was that as the light diminished in power it also became white, showing that the cerium oxide to a certain extent volatilised and, a white light having less diffusive power than a yellow one, its illuminating power, after being converted into a white light, was proportionately diminished, though the white light itself seemed more intense. In reply to Mr. Anderson's suggestion that the oxides might become reduced to the metallic state in the reducing flame, he considered that that would be impossible. But, even if such a thing did happen, they would be immediately oxidised again to the oxide, just as magnesium ribbon would be, as nearly all the rare metals possessed the property of being readily converted into the oxide when held in a Bunsen flame. As to the photometric power of the mantles and the oxides, that had been dealt with in the paper. It was generally, with the mantle, from 8 to 10 candles per cubic foot, decreasing in time to the extent of from 19 to 30 per cent. With respect to the variability of the diminution of light in certain mantles, that could not be satisfactorily accounted for in some cases. Two mantles might be made from the same fluid, one of which would burn and remain intact for about 3,000 hours, while the other would go to pieces in a few weeks. That was possibly due to the condition of the burner; if too much gas or not enough air was present, the illuminating power would rapidly go down. As he had already pointed out, perfect combustion of the gas was necessary to obtain a good result.

In reply to the question as to the extraction of the broken mantles, he would say that the mantles were first treated with sulphuric acid, evaporated to dryness, and dissolved in water. The solution of the sulphates was then treated with caustic soda and the precipitated hydrates washed to get rid of the soluble sulphates. The hydrate was then dissolved in hydrochloric acid and treated with hyposulphite of soda to precipitate the thorium and zirconium. The filtrate was retained and treated with ammonium oxalate to precipitate the lanthanum, yttrium, and cerium oxides. Those oxalates were then ignited and dissolved in dilute nitric acid, by which means the cerium oxide was left undissolved, the lanthanum and yttrium oxides passing into solution. Another method, and one which would be found more useful in analysis, would be to treat the oxides of lanthanum, yttrium and cerium with ammonium chloride, thus converting the lanthanum and yttrium into the soluble chlorides and leaving the cerium insoluble. In reply to Mr. Morrison, zirconium gave only 15 candle power, it was thorium which gave 25 candles, and yttrium and thorium combined were the best for producing high illuminating power and stability, provided they were present in the proportions he had mentioned, but the mantles were so soft that they were difficult to keep up. The Welsbach lights were especially useful for spectroscopic and laboratory work, as they gave a very steady illumination. He quite omitted to mention that when reading the paper, and was much obliged to Mr. Sutherland for reminding him of it. They were also useful for distinguishing colours. If the spectro-scope was turned towards the mantles, which did not contain didymium or erbium the pure solar spectrum would be obtained; but, if those metals were present, of course one got the didymium or erbium lines.

In conclusion, his thanks were due to his directors for allowing him the necessary time for working out the experiments, and to Mr. Sutherland for assistance given him in the completion of the paper.

THE VOLUMETRIC ESTIMATION OF ALUMINA.

BY C. F. CROSS AND E. J. BEVAN.

Is the course of a paper on "The Economy of Pure Caustic Soda," which we had the honour of reading before the Society on April 30th, 1889, we had occasion to draw attention to the fact that the alumina present in caustic soda could be estimated by titration with standard acid, taking the difference between a titration in presence of litmus, or, better still, phenolphthalein, and one with methyl orange as indicator, as a measure of the alumina present. The actual method consisted in boiling with a slight excess of acid, allowing to cool and titrating back with soda in presence of phenolphthalein. The acid so consumed represents the total amount of alkali present. To a similar portion a slight excess of acid is added and the solution titrated back in presence of methyl orange. In this way a perfectly sharp and well-defined point is reached when the colour changes from pink to yellow.

We found that although there was a perfectly definite ratio between the excess of acid consumed in presence of methyl orange and the alumina actually present, the ratio was not normal, *i.e.*, $2 \text{ Al}_2\text{O}_3$ to 6 SO_3 , but was as $2 \text{ Al}_2\text{O}_3$ is to 5 SO_3 . Thus 1 cc. of normal acid was found to be equal to '0205* gram Al_2O_3 , instead of '172 according to the normal ratio.

The following table contains the results of the titration of solutions of caustic soda containing known weights of alumina. Column I. represents the amounts of alumina added; column II. the amounts calculated from the difference between the two titrations, using the factor corresponding to the ratio $2 \text{ Al}_2\text{O}_3 : 5 \text{ SO}_3$; and column III. the amounts calculated from the normal ratio:—

I.	II.	III.
'084	'083	'069
'168	'138	'132
'321	'113	'312

When we wrote our paper we were under the impression that we were the first to observe this abnormal behaviour of alumina. An abstract of our paper appeared in the Bulletin de la Société Industrielle de Rouen, 5, 1889, 102, and in a footnote our attention was drawn to the statement that a M. Blondel had already observed the same fact. His communication was, however, only an abstract of a paper by K. J. Bayer, which appeared in the Monit. Scient. 1886, 8, 1133.

Between Bayer's original method and that credited to him by Blondel there is, however, a very remarkable and instructive point of difference. Bayer used litmus and tropæolin, and obtained normal results, whereas Blondel, who must have repeated the experiments, used litmus and methyl orange, and obtained results identical with our own. The importance of this difference will appear subsequently.

Professor Lunge, having overlooked all previous observers' work, published as original, in the Zeits. f. angew. Chem., 8, (8, 227), the same process as our own. He used phenolphthalein and methyl orange, but obtained normal results.

In the same Journal, 10, 1890, he acknowledges his want of originality, and publishes a number of observations, the object of which was to prove that we were in error. His paper has been abstracted in a number of English journals, including that of the Society.

Upon seeing Professor Lunge's results, and knowing him to be a very careful observer, we repeated our former experiments with precisely the same results. We then corresponded with him with a view, if possible, of settling the point at issue between us.

After many letters had passed, it occurred to us that possibly the cause of the discrepancy lay in the samples of

methyl orange employed. We purchased several specimens from various dealers, and found that they were of widely different composition, giving very different titration results. One specimen we obtained gave too high a percentage of alumina, using the factor calculated from the 2 to 5 ratio, but correct results using that calculated from the normal ratio. We subsequently found that this specimen was not methyl orange at all, but was tropæolin OO. This then seemed a probable explanation of the discrepancy, and we therefore exchanged samples of methyl orange with Dr. Lunge.

Strange to say, this brought us no nearer the solution, as we still differed although using each other's methyl orange, and the point at issue resolved itself into one of simple observation.

We probably should not have troubled the Society with a further discussion of the question had not Professor Lunge seen fit, in a paper read before the Newcastle Section and published in this Journal (Nov. 29, 1890), to refer again to the subject and to reiterate the statement that we were in error. We therefore, not unnaturally, claim the right to be heard in defence of our position.

In order to remove any possibility of doubt we prepared a solution of alumina in soda by dissolving an unknown quantity of sodium aluminate in water. A portion of this we retained, and a portion we sent to our friends Drs. Evans and Wirtz, of Great Ormond Street, who were good enough to estimate the alumina in it, both volumetrically and gravimetrically. Their results, and also those done in our laboratory, we give in the following table. In the case of our own results the letters indicate different observers. It may be worth while remarking that the only instructions given were to add excess of acid and titrate back, the exact point being left entirely to the discretion of the observers.

Drs. Evans and Wirtz.	Cross and Bevan.				
	A.	B.	C.	D.	Mean.
25 cc. consumed, using methyl orange, 82.5 cc. N. acid.	82.3	82.6	82.37	82.3	82.4
25 cc. consumed, phenolphthalein, 35.5 cc. N. acid.	36.0	35.7	36.1	35.5	35.8

We now give the amounts of alumina as determined gravimetrically, and those calculated from the difference between the two titrations.

Al_2O_3 in 25 cc. methyl orange—phenolphthalein $\times .205 = .9546$	$\times .1716 = .9888$
Determined gravimetrically, Evans and Wirtz .9400	
" " Cross and Bevan .9560	

These numbers speak for themselves. We will merely remark that if Dr. Lunge's contention be correct the number of cc. consumed in presence of methyl orange should have been 91.4 instead of 82.4. It is hardly conceivable that two chemists could differ to such an enormous extent in such a simple operation as a titration with normal acid.

In conclusion we would call attention to a statement by Dr. Lunge in the paper already referred to (November, 1890, 1018) that "the soda in these compounds (silicate and aluminate) in well-nigh all practical cases acts like the hydrate." This statement, which practically amounts to saying that soda which is already combined with an acid is as powerfully alkaline as the pure hydrate, will indeed be news to the soap-maker and paper-maker.

DISCUSSION.

The CHAIRMAN said that the question of the determination of alumina had led to considerable controversy in various trades. He would instance the manure trade, in which a heated discussion as to the proper methods to follow was at present proceeding. As most of the members were interested in the question before the meeting, he hoped that they would contribute to the discussion.

* This number is calculated from an atomic weight of 27.3 for aluminium, oxygen being 16 and sulphur 32. It is somewhat more correct than the number previously given, viz., '0612.

Mr. BERTRAM BLOUNT thought that the evidence brought before the meeting was so conclusive that it admitted of no discussion. Messrs. Cross and Bevan had shown that the reaction was reached at a certain point laid down in their formula, and in the absence of any evidence similarly adduced by Dr. Lunge, the matter must be regarded as settled.

Mr. D. HOWARD said that there appeared to him to be a sort of half change of colour in the liquid treated by Dr. Lunge's method. It seemed to be one of those cases which were as interesting as they were deceptive, in which a partial effect occurred; the change of colour being so slight as to make it a very undesirable one to work to. But that there was a certain change or neutral tint produced was, he thought, evident.

Mr. BERTRAM BLOUNT observed that there were a certain number of people who were unable to distinguish the colour change in methyl orange. He himself knew more than one chemist who suffered from that particular disability, although perfectly competent in every other respect. The difference of opinion which existed in the present instance might therefore possibly be due to defective vision on the part of the observer.

Mr. A. H. ALLEN said that he used methyl orange constantly in his laboratory, and never experienced any difficulty in seeing the end reaction. But he had known complaints to be made by other chemists that they could not obtain good results with methyl orange, and in one or two instances he had received samples of the colouring matter from other chemists, which samples were certainly unfit for use, the end reaction being very indefinite. It was therefore quite possible that the fault in the present case might lie quite as much with the so-called methyl orange as with the eyesight of the individual observers.

Mr. BERNARD DYER said that the great point in using methyl orange was that it should be sufficiently dilute. It was a very common error to use too much of it, and in that case it became difficult to distinguish between the vanishing of the pink and the coming of the yellow tint. With the proper degree of dilution, however, the change was very striking.

Mr. A. P. HOSKINS, referring to Mr. Allen's remarks, said that he had recently received a sample of methyl orange from a London firm with which he had failed to get any definite reaction. Thinking it possible that the difficulty might be due to there being more than one substance present, he made a rough separation with alcohol, with the result that he got two bodies which gave exactly opposite reactions—one, the ordinary methyl orange reaction, and the other the inverse of that. It was just possible, therefore, that the differences mentioned by Messrs. Cross and Bevan were due to a similar cause.

Mr. ALLEN inquired whether the true methyl orange was soluble in alcohol.

Mr. HOSKINS replied that he would not like to say positively at the moment.

Mr. C. F. CROSS said it seemed odd that a change so definite and sharp should not be got by so practised an observer as Dr. Lunge. The controversy being on a simple matter of fact, the testimony of one or two independent observers would decide it. He would be glad therefore if some of the members present would be so good as to make a few observations with a view to setting the matter at rest.

Mr. BERNARD DYER observed that there were two directions in which abnormal eyesight might affect an observation of this sort. Some people suffered from lack of sensitiveness to colour changes, but others might be ultra-sensitive to them, and thus be able to read very distinctly that partial or "half-way" change of colour which Mr. Bevan had produced in his second experiment.

Mr. E. J. BEVAN, in reply, referring to Mr. Howard's remark as to the partial colour change produced, asked whether he would consider that an end reaction.

Mr. HOWARD: No, I should not.

Mr. BEVAN, continuing, said that Mr. Blount's suggestion that Dr. Lunge was not sensitive to colour change could hardly be correct, for the numbers which he had given them, but not allowed them to publish, were wonderfully concordant. With regard to differences in the constitution of the methyl orange employed by different observers, that was undoubtedly a source of error; and he would advise all chemists to test their methyl orange before using it. In one case they had obtained a sample which turned out to be tropaeolin. With that sample they found that if they used the method he had described, though the reaction was not a sharp one, yet the results were normal, viz., 6:2, not 5:2. On discovering that, they thought they had arrived at a possible solution of the difficulty, so they sent Dr. Lunge a sample of their reagent in exchange for a sample of his. But no change in the respective results followed. Dr. Lunge got precisely similar results with their methyl orange as with his own; and by using Dr. Lunge's reagent they had been able to confirm their own original numbers. The matter therefore resolved itself into one of individual observation.

ESTIMATION OF GLYCERIN BY ALKALINE PERMANGANATE.

BY WILLIAM JOHNSTONE, PH.D., D.S.C., F.I.C.

My object in appearing before you this evening is to publicly withdraw a statement I made a short time ago in this room when taking part in the discussion on Mr. Wanklyn's paper on the "Constitution of Butter."

I stated that evening that I had no difficulty in obtaining the theoretical quantity of glycerin from butter fat by using the well known process of Benedikt and Zsigmondy (Chem. Zeit. 9, 975; this Journal, 4, 610). That statement, gentlemen, with your permission, I wholly withdraw, as the process, although an accurate one for the estimation of glycerin in certain circumstances, is totally inapplicable for the estimation of glycerin in a butter fat or in oils containing soluble fatty acids. The process originated, I believe, with Mr. Wanklyn, and was experimented on by Mr. W. Fox (Chem. News, 53, 15), who obtained discouraging results, and abandoned the process, which was then taken up by Benedikt and Zsigmondy, who worked it into shape, and finally it was taken up by Mr. Allen, leaving his hands as a full-blown accurate process for the estimation of glycerin in oils and fats.

The process is a simple one, depending upon the saponification of the fat with an alkali and the subsequent oxidation of the resulting glycerin into oxalic acid by boiling with alkaline permanganate thus:— $C_3H_5O_2 + 2 K_2MnO_4 = K_2C_2O_4 + K_2CO_3 + 4 MnO_2 + 4 H_2O$. The excess of permanganate is destroyed by sulphurous acid or a sulphite, and the manganese oxide filtered off, the filtrate acidified with acetic acid, and the oxalic acid precipitated by calcium, the resulting oxalate filtered off, dissolved in dilute sulphuric acid, and the oxalic acid titrated with standard permanganate.

Mr. Allen states: "When, however, the method is employed for determining the glycerin produced by the saponification of oils a serious practical difficulty arises. Ordinary (ethyl) alcohol yields a considerable, though variable, proportion of oxalic acid by oxidation, and if, as recommended by Wanklyn and Fox, alcoholic potash be employed for effecting saponification, it becomes practically impossible to eliminate all traces of alcohol by evaporation, without incurring or risking the loss of an appreciable quantity of glycerin; to avoid this difficulty Benedikt and Zsigmondy employ pure methyl alcohol.

As is well known, the estimation of glycerin produced by the saponification of oils and fats was a very unsatisfactory operation, chiefly owing to the loss of glycerin by volatilisation: however, the problem was supposed to be satisfactorily solved by employing Mr. Allen's *improved process*, but as far as I can see at present we are still in the same predicament, as the process is totally inapplicable for the estimation of glycerin in oils and fats containing soluble fatty acids, particularly in the presence of butyric acid, as it is readily converted into oxalic acid by boiling with alkaline permanganate, 1 molecule of butyric acid being converted into 2 molecules of oxalic acid with liberation of four atoms of hydrogen thus—

Two experiments gave the following results:—

Butyric acid, taken	*1858	*3916
„ found	*1740	*3684
Per cent.	93.64	94.07

So much therefore for Mr. Allen's improvement upon Messrs. Benedikt and Zsigmondy's process for the estimation of glycerin in oils and fats. From these results I am therefore now more inclined to support Mr. Wanklyn's statement, that the theoretical quantity of glycerin cannot be obtained from a butter fat, and that the large amount of soluble fatty acids calculated as butyric acid lately found by myself goes a long way to support his *iso-glyceride* theory.

I am at present experimenting with alkaline manganate of potash in the *cold*, and have got fairly concordant results, butyric acid apparently not being converted into oxalic acid by treatment with alkaline manganate; the results however are much below the supposed theoretical quantity, and when the experiments are completed I shall have much pleasure in laying the results before the Society at some future date.

DISCUSSION.

Mr. A. H. ALLEN said that as his name had been mentioned in the communication, he would like to make one or two observations. In the first place, he would point out that Dr. Johnstone was not accurate in his account of the part he (Mr. Allen) had had in perfecting the method of estimating the glycerin, produced by the saponification of oils, by oxidising it to oxalic acid by permanganate in alkaline solution. This was the more remarkable, as the correct account was given by him (Mr. Allen) on the very page of the Journal (Vol. V, page 70) from which Dr. Johnstone had quoted a passage in his paper. He (Mr. Allen) there stated that "the problem (of the estimation of glycerin) had, however, been recently solved in a fairly satisfactory manner by Mr. J. A. Wanklyn, further worked out by Mr. W. Fox, and perfected by Benedikt and Zsigmondy." He failed to see, therefore, the basis of Dr. Johnstone's remarks, as the only modification—whether "improvement" or otherwise—to which he (Mr. Allen) laid claim was saponification by aqueous potash, to avoid the interfering action of alcohol. He had however, very carefully investigated the process of Benedikt and Zsigmondy, and found that he got accurate results by their method. Working in the way prescribed by them, he had obtained from pure glycerin the theoretical quantity of oxalic acid, and had shown that the product did not undergo any further change by treating it with alkaline permanganate. With respect to the erroneous results which were obtained, according to Dr. Johnstone, in the case of butter fat, owing to the formation by the saponification of butter of a soluble fatty acid which yielded oxalic acid on oxidation, he would point out that it was not so much a question of "Mr. Allen's improvement on Benedikt and Zsigmondy's process," as of the accuracy of Benedikt and Zsigmondy's statement that butyric acid was not acted on by alkaline permanganate. He (Mr. Allen) had simply quoted Benedikt and Zsigmondy, who had made a positive statement based on experiment that butyric acid, acetic acid, and caproic acid underwent no oxidation and formed no oxalic acid or other acid precipitated by him from acetic acid

solution when treated with permanganate in alkaline solution under the conditions of their process. If, therefore, Dr. Johnstone had found that oxalic acid was undoubtedly formed under such circumstances, the result was that he was in a position to controvert the statement made by them, and their process would be proved unsuitable for estimating the glycerin produced by the saponification of butter, though applicable to other fats. But it was very difficult to understand how that could be the case, especially if Dr. Johnstone had used normal butyric acid. Dr. Johnstone had not mentioned the source of his acid, and it was therefore just possible that it was isobutyric acid, in which case it was just conceivable, though very improbable, that it might yield oxalic acid as the product of its oxidation. But isobutyric acid was stated, on good authority, to form an hydroxy-iso-acid by oxidation with permanganate in an alkaline solution, and as the calcium salt of the acid thus produced was readily soluble, it could hardly have been mistaken by the author for calcium oxalate. It was quite clear therefore that Dr. Johnstone was quite as much at variance with Messrs. Benedikt and Zsigmondy and the text-books as Dr. Lange had just been shown to be with Messrs. Cross and Bevan respecting the volumetric estimation of alumina. He himself had taken some interest in the matter, and might say that Mr. Hehner had recently made some experiments, the results of which absolutely contradicted those now brought forward by Dr. Johnstone. In consequence of the statement made by Dr. Johnstone, Mr. Hehner had tried to oxidise butyric acid by means of alkaline permanganate in the manner pointed out, and had failed to obtain the least trace of oxalic acid. It was clear therefore that there was a direct conflict as to the facts, and he for his part should await with interest the development of the question, which admitted of being definitely settled one way or the other without difficulty.

Dr. W. JOHNSTONE, in reply, said that he had not tested the butyric acid used in the experiments to ascertain whether it was normal or iso. He could only say that he had bought it for normal, and it had been in his possession for a long time.

NOTE BY DR. JOHNSTONE.

Since the reading of my paper I have subjected the butyric acid used to the action of dilute sulphuric acid, and a known quantity of bichromate of potash, and boiled for six hours. The amount of bichromate remaining in the flask was then estimated, and found to be practically the same, proving beyond the shadow of a doubt that it was the normal acid which I had employed in my experiments. The iso acid also requires 3 parts of water to dissolve one of the acid; on the other hand the normal acid is readily soluble.

Meeting held on Monday, 2nd March, 1891.

MR. TYLER IN THE CHAIR.

THE CHEMICAL CHANGES BETWEEN NITRIC ACID AND METALS.

BY A. H. VEELEY, M.A., THE UNIVERSITY MUSEUM, OXFORD.

I HAVE a three-fold object in bringing before you to-night a subject so trite, so common-place, so appertaining to the very nursery of chemistry as the action of nitric acid on metals. My first object will be, so far as circumstances permit, to give you an experimental demonstration of certain statements of mine upon this subject. My second object is to offer an opportunity to those who may differ from my views for passing criticism upon them; and my third object will be to trace in outline the investigations upon which I am now more particularly engaged, and to indicate their practical utility.

I suppose that it has fallen to the lot of most of us at some time of our past to have learned that when moderately concentrated nitric acid is poured on copper there is an evolution of nitric oxide gas, and I suppose also that it has fallen to the lot of some of us either to have taught or to have been taught that the formation of nitric oxide under these conditions is due primarily to the replacement of the hydrogen of the nitric acid by the copper, the liberated hydrogen reducing the nitric acid to nitric oxide. It will be my endeavour to-night to disprove as far as possible the statement, and then to controvert the explanation.

Nearly 20 years ago, Dr. Russell (*Jour. Chem. Soc.* 1874, 3) showed that if a current of hydrogen gas be passed through a dilute solution of silver, nitrate metallic silver is precipitated. The logical consequence of such a result would be that silver does not dissolve in moderately dilute nitric acid. Further, Dr. Russell found that the amount of hydrogen thus absorbed was not commensurate with the amount of silver precipitated—in fact that some of the hydrogen reduces the nitric to nitrous acid, which in its turn is blown off by the current of hydrogen gas. If it is not thus carried away by the stream of hydrogen gas, the silver re-dissolves in the nitrous acid formed.

About two years ago (*Proc. Roy. Soc.* 46, 218), in the course of some experiments made for an entirely different purpose, upon the solution of copper in nitric acid, I observed that when pure metallic copper was placed in moderately concentrated nitric acid, at first no gas was evolved, and, further, that the amount of copper dissolved in those initial stages of the operation was less than the amount of copper which was dissolved when the copper was placed in a solution in which some of the metal had previously been dissolved.

The method adopted for purifying the nitric acid was comparatively simple; it consisted in warming up the acid to 35° and blowing a current of air through it. The concentrated nitric acid was then added to a quantity of water to produce the degree of concentration which was thought desirable.

I have here some nitric acid which has been purified in this way, and I will endeavour to show that it contains no appreciable quantity of nitrous acid. In these cylinders I have some water, and into each of them I will put a comparatively large dose of nitric acid. In the one case, I will add solutions of starch and iodide of potassium usually employed for testing for the presence of nitrous acid, and it will be seen that the amount of nitrous acid present in this case at least, is comparatively small. Another delicate test is the carbon compound known as meta-phenylenediamine hydrochloride ($C_6H_3N_3 \cdot 2HCl$), and I therefore introduce some of it into the other sample of nitric acid. It should produce a yellow-red colouration if nitrous acid be present, but the amount of colouration produced is inappreciable.

It was found that if the metals copper, mercury, and bismuth were placed in such purified nitric acid under such conditions that the metal and the nitric acid were both kept in agitation, no chemical change took place. In the case of copper, the criteria of there being no chemical change were, firstly, that there was no gas evolved; secondly, that no blue colour was imparted to the solution; and thirdly, that the weight of one of these copper spheres, when thus treated, was exactly the same at the end as at the beginning of the experiment, provided that no nitrous acid was present initially, and that no nitrous acid was formed during the experiment. To prevent such formation of nitrous acid, I found it necessary, in the cases of copper and bismuth, to add a small proportion of some substance which would react with the nitrous acid and destroy it as fast as it was formed. Such substances are urea, potassium chlorate, hydrogen peroxide, &c.

[A photograph of the apparatus used, which is figured in the *Journal of the Chemical Society*, 1889, 365, was here thrown upon the screen.]

The principal parts of the apparatus consist of the wooden cone, upon which works, by friction only, a brass disc, through which passes a brass rod. This cone is driven by a tangent screw, connected with a water motor. When the

cone is rotated it causes the disc to rotate. At the lower end of the brass rod there is a glass rod, bearing at its lower end a small glass dish, upon which is placed the sphere of copper or other metal; the whole is immersed in a beaker. The glass rod is set slightly skew-wise, in order that the metal sphere should not always rotate on the same axis. A current of carbonic acid is delivered through a funnel, in order to keep the nitric acid in perpetual agitation. Under these circumstances, provided that the nitric acid is kept well stirred, and the metal is in continual agitation, I found that using nitric acid of 30 per cent. concentration there is no reaction between the metal and the acid, if a small quantity of urea, potassium chlorate, hydrogen peroxide, or other substance capable of removing any nitrous acid be added.

Here is a small trough divided into three divisions, and into each division I introduce a small quantity of nitric acid. Then into one of these divisions I place a small quantity of sodium nitrite, in order to give the required quantity of nitrous acid; into another division I introduce a small quantity of potassium chlorate, which will destroy any nitrous acid which may be formed; and in the third division I leave the acid as it is. Then in each division I place a small strip of copper, and throw the image of the whole upon the screen. The experiment is, however, shown at a disadvantage in that I am not able to keep either the metal or the acid in motion, and the purified acid cannot bear a railway journey without formation of some nitrous acid.

It is evident that in the case of the division containing the nitrite, there is a rapid stream of bubbles, whereas from the copper in the pure nitric acid but few bubbles arise, and in the third tube the reaction has not as yet started. This shows the effect produced upon copper and nitric acid by the presence of a small quantity of sodium nitrite.

I propose next to show a precisely similar experiment with metallic mercury. Into each division I will put some nitric acid, as before, and to one I will add a little sodium nitrite, and to the other a small quantity of potassium chlorate. Then into each I introduce a small quantity of carefully purified mercury. In the division containing the nitrite the whole field is studded with bubbles, whereas in the other case, in which a little potassium chlorate was introduced, no bubbles are formed. This shows the effect of a small trace of chlorate of potash, which prevents nitrous acid from being formed, and thus the mercury from being dissolved.

But it may be argued, and with reason, that the non-evolution of gas is not necessarily a criterion that no metal has been dissolved. I propose, therefore, to illustrate this point by an experiment in a somewhat different form. Into these three cylinders I place a small quantity of purified nitric acid, and into one I put as before a small quantity of my nitrite solution, into the other some urea, and the third is left as it is. Into each cylinder a copper sphere is introduced. It will be seen that there is a great evolution of gas in the case of the cylinder containing the nitrite, while in the other two cylinders there is little or no gas formed. The nitric acid in each of the cylinders is neutralised with ammonia, and it is manifest that there has been a far greater amount of copper dissolved in the one case than in the others.

A similar experiment can be shown with mercury. I take three cylinders as before, and place in each some nitric acid. Into one I put a small quantity of nitrite, and to the other I add some hydrogen peroxide, and in each a little mercury is placed. Bubbles come freely from the cylinder containing the nitrite, while the surface of the solution in the cylinder containing the peroxide and that containing the nitric acid only are nearly or quite free from bubbles.

The case of bismuth is precisely similar. Some nitric acid is placed in each of these three cylinders, and into one I will put some sodium nitrite, into the second some urea, and the third I will leave as it is. I introduce spheres of bismuth; and it is evident that the evolution of gas commences at once in the cylinder with the nitrite, while in the other two cylinders it is hardly perceptible.

The acid solution from the three cylinders containing the mercury is poured off and tested with dilute hydrochloric acid, since mercury dissolves initially as mercurous nitrate. From the first cylinder an abundant precipitate of mercurous chloride is obtained, from the next cylinder hardly any, and from the third no precipitate, a result which illustrates the effect produced on the solution of the mercury by the presence of a small quantity of nitrous acid. I will likewise test the three cylinders containing the bi-muth spheres with a solution of hydrogen sulphide. There is an abundant precipitate of bi-muth sulphide in the first cylinder, far less in the second, and only a colouration in the third case. [Experiments shown.] Thus, in the case of bi-muth also the presence of small quantities of nitrous acid, on the one hand, or of a substance that will destroy it as it is formed, on the other hand, produces a considerable difference in the amount of metal dissolved.

If, then, these metals will not dissolve in nitric acid, but will dissolve in nitrous acid, and if one starts with pure acid, how does the change commence? First, it may be that the metal can seize a quantity of nitrous acid which cannot be detected by even the meta-phenylenediamine reaction; or it may be that the metals contain a small quantity of impurity, which produces a couple, thus electrolysing the nitric acid to produce nitrous acid, and starting the reaction. I am inclined to favour this latter hypothesis, as I have been more successful with mercury than with copper, and with copper than with bi-muth; and that is the probable order of purity of the metals.

My experiments also showed that the amount of mercury, copper, or bi-muth dissolved, and the amount of nitrous acid formed, were concomitant variables.

The net result of the investigations appears to be that the nitrous acid is decomposed as fast as it is formed. In fact the whole explanation of the solution of these metals, copper, mercury, bi-muth, and silver, depends upon the presence of this small quantity, 1 or 2 parts per 10,000, of the effective reagent nitrous acid.

The equations representing the changes are probably reversible thus:—

It will be remembered that Dr. Divers (Jour. Chem. Soc. 1883, 465) distinguishes metals as regards their reaction with nitric acid into two classes. The first class, with which I have dealt this evening, consists of copper, mercury, bi-muth, and silver, which convert the nitric acid to nitrous acid; the other class includes the metals zinc, lead, cadmium, magnesium, iron, &c., which do not, according to Dr. Divers' experiments, yield an appreciable quantity of nitrous acid when they dissolve in nitric acid. On the other hand, Dr. Armstrong has stated, in a foot-note to the same paper by Dr. Divers, that he finds that the primary product of the reduction of nitric acid is nitrous acid, and that this body is invariably formed when any metal is dissolved in nitric acid. My results showed that all metals dissolve in nitric acid to form nitrous acid as the primary product of the reaction; and I will illustrate this by selecting those metals belonging to the second class of Dr. Divers' acid.

To this end, I place in one tube some metallic cadmium five times purified by distillation in vacuo, in a second tube some zinc, distilled four or five times in vacuo, into the third tube some steel wire, and in the fourth nitric acid.

[The contents of the tube were warmed up and then tested with meta-phenylenediamine to show that in all these cases nitrous acid was formed, except in the tube containing the nitric acid only.]

I propose, now, to show that the nitric acid, so far from dissolving the metals, actually prevents their being dissolved. I will place in one tube a small quantity of nitrous acid, in another some nitrous acid and some nitric acid, and in the third I will put some nitric acid only. The whole point of the experiment will rest on the fact that in the one case the metal dissolves rapidly in the solution of nitrous

acid, that it dissolves less rapidly in the mixture of nitric and nitrous acids, and thirdly, that it dissolves still less rapidly in the nitric acid alone. This nitrous acid was obtained by the decomposition of silver nitrite. [Experiment shown.]

I would also draw your attention to some specimens which Mr. Cross has been kind enough to lend me, and which show another effect of adding to nitric acid a small quantity of some substance which shall either remove the nitrous acid as fast as it is formed, or else prevent its formation. Mr. Cross has found that if jute fibre be treated with nitric acid there is formed, among other substances, a yellow nitroso-product. In the case of sulphuric acid, the cellulose is simply hydrolysed. If a small quantity of urea is added to the nitric acid, then the action of the nitric acid upon the fibre is the same as the action of sulphuric acid. In fact, I incline to believe that many of the chemical changes in organic chemistry which we are accustomed to represent as taking place between nitric acid and the organic substances are conditioned by the presence of the nitrous acid.*

It may appear to be a presumption on my part that I, "a scholastic or professorial chemist" (adopting the classification of a recent writer), should venture to address a body of industrial chemists. So far as I can gather from the writer in question, the merit of the scholastic chemist is that he delivers drowsy lectures to half-slumbering audiences. If, however, to this somewhat soporific draught of scholastic chemistry I have succeeded in adding the slightest tincture of that which is practical, then this paper will not have been given in vain.

THE CHEMICAL CHANGES BETWEEN LEAD AND NITRIC ACID.

BY A. H. VEEY, M.A., THE UNIVERSITY MUSEUM, OXFORD.

THE condition of reaction between metallic lead and nitric acid, whether pure or contaminated with small proportions of nitrous acid, present some points of importance on account of the use of this metal for the construction of acid-containing vessels. The effect also of the presence of nitric and nitrous acids in inducing the solution of metallic lead in sulphuric acid has attracted the attention of vitriol makers so long as the present methods of manufacture have been in vogue. In the present communication it is proposed to give a preliminary account of some experiments on the former of these problems, and to reserve the latter for some future date.

Spheres of pure metallic lead were supplied by Messrs. Johnson and Matthey; the nitric acid used was purified according to the process described. The specific gravity of each sample of acid was determined by means of a delicate pyrometer, and the percentage of free acid, calculated as HNO_3 , was also estimated for the same portion by the usual process of acidimetry. At the outset a series of experiments were made to determine the effect of concentration of the acid, the temperature being kept constant. The apparatus and method of working is described in detail in my paper "On a Method of Investigating the Dissolution of Metals in Acids;"† the same volume of 750 cc. was used throughout, and the duration of each experiment was one hour.

* Since the date of the meeting my attention has been drawn to experiments of Dönniger (J. für Chem., 2, 42, 550–553), which show that certain hydroxybenzoic acid can be nitrated by nitrous acid.

The above results show that as the concentration of the acid is increased, the temperature being kept uniform, the amount of lead dissolved per unit time increases up to a maximum point and thence decreases. The behaviour of this metal under these conditions is unlike that of copper, mercury, and bismuth. The net result, however, in the case of lead is dependent upon two opposing causes: (1) the intensity of the chemical change between the metal and the acid which would tend to increase with increase of concentration; and (2) the decrease in solubility of the lead nitrate formed in the acid liquor under the same conditions. In order to obtain a more particular insight into the effect produced by the latter cause, the solubility of lead nitrate in four out of five samples of nitric acid was determined for the temperature of 35° , and compared with that of water under the same conditions.

Plate I.

Curve of Chemical Action between Lead and Nitric Acid of various concentrations.

The results are compared in the following table:—

SOLUBILITY OF LEAD NITRATE EXPRESSED IN PARTS DISSOLVED PER 100 PARTS SOLVENT.

Concentration of Acid.	Solubility.
Per Cent.	
0	64.39
15.76	10.25
22.76	5.98
29	3.01
40.31	1.62

The curve representing the solubility of the salt in terms of percentage proportion of nitric acid does not seem to be expressible by any simple form of equation; the phenomenon is possibly complicated by the formation of acid nitrates.

The effect of increase of temperature, concentration of acid remaining the same, increases as would, *a priori*, be expected, the amount of lead dissolved. The following series may serve as a comparison with those of Series V., the only alteration of condition being that of temperature.

SERIES VII.

Specific gravity of acid $\frac{1}{16}$ 1.2516. Concentration per cent. 40.81. Temperature 40.

Weight of Sphere at Commencement.	Weight of Sphere at Conclusion.	Loss.	Mean Area in Mm. Sq.	Decimilligrammes dissolved per 1 Mm. Sq.

Mean value,				7.32

These experiments, taken from a chemical standpoint, are quite in accordance with Faraday's investigations on the electro-chemical position of lead, which showed that the metal, when immersed both in concentrated and in dilute nitric acid, was electro-positive to the metal immersed in acids of intermediate strength. (Experimental Researches, Series XVII.)

Plate II.

Curve of Solubility of Lead Nitrate.

As previous experiments had shown that when lead dissolves in nitric acid, nitrous acid is produced, while the investigations upon the metals copper, mercury and bismuth had proved that the amounts of metal dissolved and of nitrous acid present were concomitant variable determinations of the nitrous acid were made in the course of the experiments recorded in Series V. and VII. The following results were obtained:—

60	·053	60	·047				

The above results show that the amount of nitrous acid present increases gradually up to a maximum and constant point; the amount, however, is, under the conditions of experiment, comparatively small. From the results to be described in the sequel it follows that this slight increase in the amount of nitrous acid would have no material effect upon the amount of lead dissolved.

Effect produced by Rest.—In all the above series of experiments both the metal and acid were kept in motion. As the results of the investigations with the metals, copper, mercury, and bismuth had shown that the amount of metal dissolved by the nitric acid is increased to a marked extent by keeping both metal and acid at rest. On account of the increase of the amount of nitrous acid in the immediate vicinity of the metal, a comparative experiment was also made in the case of lead. The results obtained were as follows:—

(I.) CONDITION OF MOTION.

Concentration of acid, 35·35 per cent. Temp., 33°.

Weight of Sphere at Commencement.	Weight of Sphere at Conclusion.	Loss.	Mean Area.	Decimilli-grammes dissolved per 1 Min. Sq.
Grms. 5·7243	Grms. 5·4348	Grm. ·2895	285·3	10·3

(II.) CONDITION OF REST.

5·4348	5·3503	·0845	280·7	3·0
--------	--------	-------	-------	-----

The amount of metal dissolved in the second experiment is less than a third of that dissolved in the first experiment. This difference of behaviour of lead to that of the other metal is here also due to the sparing solubility of the lead nitrate in the nitric acid and the saturation of the acid in the immediate vicinity of the metal with the salt formed.

Effect produced by Addition of some Substance added to Destroy the Nitrous Acid.—A number of experiments have been made with a view of preventing metallic lead from dissolving in nitric acid by adding some substance, such as potassium chlorate or hydrogen peroxide, which should destroy the nitrous acid; but though they have thus far proved unsuccessful, yet they have shown that the amount of metal dissolved is reduced to some appreciable extent by the presence of these substances.

Effects of Addition of Small Quantities of Nitrous Acid.—In order to determine the effect produced by addition of nitrous acid, two experiments were conducted under conditions precisely identical with those of Series V. The results are given below:—

Weight of Sphere at Commencement.	Weight of Sphere at Conclusion.	Loss.	Mean Area.	Nitrous Acid. Mgrms. in 1 cc.	Decimilli-grammes dissolved.
Grms. 4·6533	Grms. 4·3828	Grm. ·2705	244·4	15·05	11·37
4·3828	4·1928	·258	233·72	21·5	11·02
Mean value					11·19
Mean value of Series V.					10·41

Thus the presence of nitrous acid increases to a slight degree the amount of lead dissolved. This point will, however, be more fully discussed in the sequel. It is worthy of remark that the effect of the presence of the nitrous acid is far less than in the case of the metals mercury, copper, and bismuth.

The Dissolution of Lead in Nitric and Nitrous Acid taken Separately and Together.—As previous investigations had shown that the metals mercury and bismuth dissolve very readily in a 1 per cent. solution of nitrous acid, and under these conditions the presence of nitric acid interferes with, rather than promotes, the interaction between the metals and the acids, a series of comparative experiments were made upon the amounts of lead dissolved in nitric and nitrous acids, either taken separately or together. Simultaneously the effect produced by alloying the lead with small proportions of antimony was also investigated. Spheres of alloys containing 5 and 10 per cent. of antimony were made from my instructions by Messrs. Johnson and Matthey, as it appeared that alloys of these compositions are in use for pumps and vessels to contain acids.

Three spheres of pure lead, the 5 and the 10 per cent. antimony alloy, were suspended, by means of a glass arrangement, within the acid mixtures contained in three tubes, and placed under identical conditions. The time of each experiment was varied, according to circumstances, for each set of experiments. The temperature varied from 12° to 15°.

The nitrous acid used was obtained by the decomposition of recrystallised silver nitrite with hydrochloric acid. For each mixture the total acidity was determined by a standard solution of soda, and the amount of nitrous acid by a standard solution of potassium permanganate; the difference between these two values gives the amount of nitric acid present.

From the above series of experiments the following conclusions may be drawn.

Firstly, metallic lead is attacked to a slight extent by nitric acid (whether concentrated or dilute), and also by nitrous acid, when the two acids are taken separately; it is attacked to a much greater extent by mixtures of the two acids, and the intensity of the reaction is the greater the more nearly is the proportion of nitric to nitrous acid.

This is especially marked in Experiment VII., in which the mixture used was obtained by the gradual addition of nitrogen peroxide to well-cooled water. This result may be due to a compound of nitrous and nitric acids as suggested by Armstrong.* In this case also the behaviour of lead is different from those of mercury, copper, and bismuth, which are attacked very readily by nitrous acid, less readily by mixtures of nitric and nitrous acids, and not at all by pure nitric acid.

Secondly, in most of the above experiments, the pure lead is less readily attacked than the alloy containing 10 per cent. of antimony, and this in its turn less than the alloy containing 5 per cent. of antimony. These differences are especially marked in the case of pure concentrated nitric acid (Experiment II.), and of the mixture of nitrous and nitric acid in nearly equivalent proportions (Experiment VII.); in the latter experiment the behaviour of the alloys was most remarkable, in that the lead dissolved with considerable evolution of gas, while the metallic antimony sealed off and fell to the bottom of the containing vessel. These scales were collected and weighed with the sphere.

It would not appear, therefore, that any especial advantage accrues in alloying lead with a small proportion of antimony for the construction of pumps or vessels through which nitric acid, whether pure or containing nitrous acid, might pass. These experiments, also, do not confirm in the particular case of nitric acid the received opinion of some writers, that whereas "most metals are all the less acted upon by acids the purer they are, but the contrary seems to be the case with lead."

The main conclusions to be drawn from the experiments described above may briefly be summed up as follows:—

(I.) The behaviour of lead towards nitric acid is different, except in the production of nitrous acid, from that of the metals, silver, mercury, copper, and bismuth.

(II.) Lead is attacked to a less degree by very dilute and concentrated nitric acid, but to a greater degree by acid of intermediate strength.

(III.) Lead is attacked to a less degree by nitric or nitrous acid, taken separately, but to a greater degree by mixtures of the two acids, the reaction between the metal and acid mixture being the more intense the more nearly equal in the proportion between the nitric and the nitrous acids.

(IV.) In the construction of vessels through which nitric acids or mixtures of nitrous and nitric acids might pass, there does not appear to be any advantage in alloying the metal with small proportions of antimony.

DISCUSSION.

Mr. C. F. Cross wished to say a few words with respect to the specimens of fibres shown by the author. The particular form of fibre treated was the typical ligno-cellulose, or jute. It would be noticed that the specimen on the left showed the ordinary action of the non-oxidising acids, while the one on the right was almost completely resolved into cellulose and the yellow derivative of the lignone molecule (which is a complicated keto-alcohol),

probably a nitroso body or an oxime. The advantage of working with carbon compounds, which had become so evident during the last 20 years, was that it enabled one to cast a light on the reactions which took place with inorganic compounds, by fixing the intermediate stages. In the case of nitric acid and the metal copper, for instance, the reaction no doubt proceeded through definite intermediate steps which could not be followed, but if one took a complicated molecule like the one in question, the number of probabilities involved in the reaction were extremely numerous. He might mention nitrites, nitroso derivatives, nitrolic acids, oximes, and the simpler nitrogen compounds, such as nitric and nitrous oxides and hydrocyanic acid, some or all of which appeared to be formed in the reaction. Dr. Will, who was now in this country, had published an important paper in the last number of the "Berichte" (p. 400), on the reaction of alkalis with the cellulose nitrates, in which he showed that the first product of the saponification, instead of being a di-nitrate as had been supposed by Eder, was an oxime, yielding oxyacetic acid, of which he had isolated the phenylhydrazide. He mentioned that as indicating the complications which were always to be expected in the action of such complex molecules as the fibre keto-alcohols and nitric acid; but it was evident that the continued study of these reactions in the case of typical bodies would give us a systematic dissection of these bodies, and at the same time elucidate the actual mechanism of the reactions of the inorganic nitrogen compounds.

Mr. G. D. MACINDOE observed that one of the results of the paper would be that those who had been in the habit of using pure nitric acid, and had found it difficult to get the reaction to commence, would in future take care to have a small portion of nitrous acid present to start the reaction. It would also be a hint to nitric acid makers to point out to their customers that it was undesirable to press them too hard on the point of supplying it pure and free from nitrous acid, because possibly many of the complaints as to the quality of pure nitric acid arose owing to the absence of the small quantity of nitrous acid which Mr. Veley's experiments proved to be essential.

Mr. A. G. BLOXAM confessed that at the moment he was more interested in the paper from the professorial than from the practical point of view. He would like to ask the author for further information as to how he accounted for the commencement of the reaction between the copper and the nitric acid. He had understood the author to say that the cause of the reaction was the impurities in the copper or other metal used. He would like to know whether there were any metals which would cause the evolution of nitrous acid from nitric acid, and if not, did Mr. Veley attribute the commencement of the reaction to voltaic action taking place between the copper and the foreign metal contained in it?

Mr. H. DE MOSENTHAL had listened with great interest to the paper, which he thought contained hints of much practical value, especially that part which referred to the reaction of nitric and nitrous acids with metals. But he thought that the author had been somewhat too general in suggesting that the same results might apply to all organic substances. He hardly thought that the results of nitration would be obtained in certain cases so readily if nitrous acid were present. In fact, the presence of nitrous acid was to be avoided in certain cases. For instance, if it were required to obtain nitro-cellulose especially with a high percentage of nitrogen, he did not think that the presence of nitrous acid would assist, even in commencing the reaction. And he certainly would not like to add very much nitrous acid to the nitric acid in the manufacture of nitro-glycerin.

Mr. BERTRAM BLOUNT asked the author whether he could give any further information as to the time occupied by the process of freeing the nitric acid from nitrous acid by means of air. He would also be glad to know whether Mr. Veley had found any other gas preferable to air for the purpose of driving off the nitrous acid.

Mr. WATSON SMITH observed that his friend Dr. Lunge, in his treatise on the sulphuric acid manufacture, had referred to the danger of over-steaming the last chamber of a series. Lunge said that the danger arose from the fact that when the sulphuric acid was reduced below a certain strength, the nitrogen compounds ceased to form nitrosyl-sulphonic acid, and at that reduced strength nitric acid instead of nitrous acid began to be found in the chamber acid, and the lead was attacked. He appeared to consider, therefore, that the solvent action on the lead was due to the nitric acid. According to Mr. Veley, however, it now seemed that nitrous acid, as such, would at once exert a powerful solvent action on the lead. Clemens Winkler had also investigated the question, which was an important one to the sulphuric acid manufacturer. It would be interesting to hear the evidence of Lunge and Winkler on the subject. If not already investigated, it seemed to him that it would be an interesting subject of inquiry to determine the exact circumstances under which the reaction of sulphuric acid containing nitrous acid in solution commenced operations on lead in contact with it, and whether nitric acid as such was really contained in chamber acid, say, of 80° or 90° Tw., in the last chamber of a set. It was certain that if nitrous acid directly attacked lead in presence of sulphuric acid, and if also it might pass, by a further step of oxidation, into nitric acid, there must be a point of equilibrium, on one side of which nitrous acid was reduced by lead and on the other nitrous acid was oxidised further to nitric acid. But it was difficult to comprehend that under the same circumstances nitrous acid could directly attack lead, suffering itself reduction, and also oxidise to nitric acid, which should then attack lead and suffer reduction. In other words, was it possible to conceive that in the same cycle of chemical changes nitrous acid was being oxidised whilst nitric acid was being reduced, if we granted, as Mr. Veley showed we must do, that nitrous acid attacked lead, whilst we were also told that nitric acid does so by other authorities?

Mr. W. CROWDER said that he could reply to Mr. Smith's question at once. The point at which nitrous acid would begin to act upon the lead was somewhere about 60° or 70° Tw. The best way of ascertaining whether one had nitrous acid present to the injury of the chambers was this: as long as nitrous acid was present the chambers were of a dark-brown red; the instant one got too much steam it cut down the nitrous acid, forming nitric acid, and then away went the curtains. He had no doubt, therefore, that Mr. Watson Smith had correctly quoted Dr. Lunge in his remarks. He regarded Mr. Veley's paper as being of very great practical value. He was much interested in questions relating to the action of nitric acid on metals, especially in connexion with sulphuric acid chambers; and the paper had thrown some light on problems having reference to that action.

Mr. A. E. FLETCHER said that in speaking of the action of nitric acid on organic compounds two separate actions had to be considered. In the one case there was the formation of a substitution compound, while in the other case they had to deal merely with the oxidising action of the nitric acid. In the formation of nitro-benzol, for instance, they required pure nitric acid, whereas for the oxidation of aniline the presence of nitrous acid was necessary, the one being a substituting, the other an oxidising action.

Mr. C. F. CROSS said that he might refer to one or two notes in his book on the influence of nitrous acid on the results of nitrating fibres. Mr. de Mosenenthal had touched an important part of the question in his remarks as to whether in the nitration of fibrous substances to form explosives, the presence or absence of nitrous acid would alter the character of the nitration in the direction of taking up more or less nitric acid in combination. He held in his hand the notes of some experiments of his, in one of which he had added 5 per cent. of nitrous acid on the nitric acid present, and in another case he had added urea. But the products of the nitration appeared to be in every respect unaltered; and, therefore, in the case of the nitration of fibrous substances the presence or absence of nitrous acid was without effect.

Mr. VEEY, in reply, said that he feared that his remarks regarding the nitration of organic compounds had been taken to a greater degree than he wished. So far as he could remember, he had said that it was just possible that nitrous acid was the effective material. It appeared, however, that some members gathered that he thought that in all cases nitrous acid was the essential substance, instead of, as he wished to convey, that it was *possibly* the essential substance. Mr. Bloxam had inquired how he explained the commencement of the reaction between the metals and the nitric acid. He had said in the course of his remarks that the commencement of the reaction might be due to either of two causes. Either the metal could lay hold of an amount of nitrous acid which could not be detected by any of the delicate reactions for nitrous acid, or, as he thought more probable, there might be a slight impurity in the copper, mercury, or other metal, whereby an electric current was produced, which formed an amount of nitrous acid sufficient for the metal to react well (*sub supra*). But with regard to the initial change being of an electric or chemical nature it was not his intention to enter into that question. He might remark, however, that in addition to the chemical investigations brought before the meeting, he had, in conjunction with Mr. Burch, made a number of experiments upon the electro-motive force of various cells containing platinum with copper, bismuth, mercury, and silver. It was found by means of a capillary or quadrant electrometer that the electro-motive force of a combination of copper, for example, nitric acid and platinum, was extremely small, viz., from 0.25 to 0.3 volt; but it increased rapidly to somewhere about 0.75 volt, provided pure nitric acid was used. If the slightest trace of nitrous acid was introduced, then the electro-motive force went to its maximum at once. The initial E.M.F. depended upon the purity of the acid. If ever the copper strips were touched by the finger, or if ever there was the slightest impurity in the glass vessels, or if ever a slight impurity resulting from some previous experiment remained on the platinum, the electro-motive force went up to its maximum at once. In answer to Mr. Blount's inquiry as to the length of time required to purify the nitric acid, he could only say that the time depended upon the purity of the atmosphere of the laboratory. It would be practically impossible to purify the acid in a laboratory, for example, wherein a number of operations in organic chemistry were going on, and it would be almost impossible in presence of direct sunlight. There was no particular advantage in air, except that it was a convenient and cheap substance for blowing out the nitrous acid. He regarded the removal of the nitrous acid under those conditions as purely a mechanical blowing out, and in no way due to the oxidation of the nitrous acid to nitric acid by the air. As to the time required he could only say that it varied very much. Under suitable conditions, provided that no one else was working in the laboratory, and that the sun was not shining too brightly, the acid could be purified in an hour, and under less favourable circumstances it might require about half as long again.

He had omitted to mention the method employed for estimating the various amounts of nitrous acid. He had made use of a colorimeter somewhat different from those in ordinary use. It consisted essentially of two mirrors and a glass case, in which were placed two tubes, one containing the solution to be examined, and the other a standard solution of known strength. The first-named tube was filled up to a certain mark with the solution, and the other one was raised or lowered as the case might be until the tint of the two discs in the mirrors appeared the same. So far as he knew, this was a more convenient method, and one susceptible of greater accuracy than the mere looking down upon columns of coloured liquids, for it was possible to adjust the level so as to obtain the discs of practically the same tint. By that means the amount of nitrous acid present could be determined within 1-2 per cent., even in the extremely dilute solutions which occurred in the course of the investigations.

ON ALDEPALMITIC ACID.

BY J. ALFRED WANKLYN.

CONTINUING the investigation of aldepalmitic acid, I find that there is a very decided difference between the palmitic acid of palm oil and aldepalmitic acid in specific gravity, viz.:—

	Sp. Gr.
Palmitic acid	0.950 at 14.5° C.
Alde-palmitic acid	0.890 at 12.5° C.

The preparation and examination of the salts has likewise been proceeded with, and the aldepalmitate of potash, soda, ammonia, baryta, strontia, lime, magnesia, silver, and copper have been in my hands.

So far as I know, except the salts of the alkalis (which appear to be partially soluble with decomposition), the aldepalmitates are insoluble in water.

The magnesia salt is soluble to, at least, 2 per cent. in hot alcohol of sp. gr. 0.83, and is deposited from the solution on cooling down to 15° C. Some of the salts of this acid, and of the accompanying acid, which, as has been described, is absorbable by bibulous paper, are soluble in benzene; and the investigation is becoming very interesting.

Aldepalmitate of baryta, $C_{16}H_{29}BaO_2$, is a white powder insoluble in water. It is prepared by pouring ethereal solution of the acid into clear baryta water (moderate excess of baryta) and boiling. The resulting precipitate of baryta salt is washed with boiling water, dried at 100° C., extracted with ether, and again dried at 100° C.

Submitted to analysis it gave 2.063 grms. taken : 0.748 grm. $BaOSO_3$ by ignition with sulphuric acid.

	Calculated.		Found.
C_{16}	192
H_{29}	29
Ba	68.5	21.31	21.32
O_2	32
	321.5

Aldepalmitate of silver, $C_{16}H_{29}AgO_2$, has been prepared by double decomposition, viz. by the action of nitrate of silver upon either the soda salt or the ammonia salt of the acid. The silver salt forms a very bulky white precipitate and indeed comes down in combination with alcohol if the precipitation be made in presence of alcohol.

The quantity of alcohol (and possibly also water) which is consolidated by this salt is most remarkable. Thus in one of the experiments the figures were:—

Weight of aldepalmitic acid = 2.7 grms., which was dissolved in alcohol and poured into a solution of nitrate of silver, a little ammonia being added. Weight of precipitate after washing and pressing with bibulous paper = 22 grms.

The 22 grms. of this strange silver salt when dried in the water-bath lost weight until it weighed 5 grms. It was then extracted with ether and again dried at 100° F. and finally weighed 3 grms., there having been a little mechanical loss.

The silver salt is thus shown to possess the extraordinary power of consolidating about five times its weight of alcohol (or of mixed alcohol and water).

This property of the silver salt is a hindrance to its employment as a means of investigating the equivalent of the acid, inasmuch as the enormous proportion of consolidated alcohol carries down foreign matter and contaminates the salt.

In the instance in which the soda salt was employed the resulting silver salt exhibited excess of residue on ignition. And in the instance when the ammonia salt was employed

the residue on ignition was deficient. The following are the data:—

I. Silver salt (from soda salt)—

	Grms.
Substance taken.....	1.412
Residue on ignition (Ag)	0.441

II. Silver salt (from ammonia salt)—

	Grms.
Substance taken.....	1.152
Residual silver.....	0.341

	Calculated.		Found.	
			I.	II.
C ₁₆	192
H ₂₉	29
Ag	108	29.92	30.58	29.52
O ₂	32
	361	100.00

If it should be deemed advisable to resort to the silver salt for the purpose of investigating the equivalent of aldepalmitic acid, I should try another method of preparation, and would take ethereal solution of the acid and oxide of silver.

This silver salt is not sensitive to light and will bear drying at 100° C. without changing its colour.

Aldepalmitate of lime, C₁₆H₂₉CaO₂, is a white powder, insoluble in water. It is prepared by boiling the acid with lime water and removing any excess of acid by means of extraction with ether. It is dried at 100° C.

It gave on analysis:—1.159 grm. gives 0.295 grm. CaOSO₃.

	Calculated.		Found.
C ₁₆	192
H ₂₉	29
Ca	20	7.33	7.49
O ₂	32
	273

Apparently the lime salt is capable of combining with alcohol, giving a compound of one molecule of the salt with four of alcohol.

Aldepalmitate of strontia, C₁₆H₂₉SrO₂. The strontia salt is very peculiar. It was prepared by dissolving the acid in hot alcohol, filtering into strontia water and boiling. The bulky precipitate was pressed with bibulous paper and weighed, and then dried at 100° C. and again weighed.

The salt thus prepared was found to contain a small excess of strontia, yielding 16.2 per cent. of strontium. The theory requires 14.8 per cent. of strontium.

Another preparation of the salt gave 14.3 per cent. of strontium.

This salt is remarkable in several ways. Apparently it has no tendency to unite with alcohol, but combines with about its own weight of water, forming a massive white precipitate. Prolonged drying in the water-bath gets rid of all this water and the salt suffers a very manifest alteration and becomes like calcined magnesia in aspect.

Aldepalmitate of magnesia, C₁₆H₂₉MgO₂, prepared by boiling calcined magnesia with an excess of the acid in alcoholic solution. The hot alcoholic solution deposits the

magnesia salt on cooling. It is a white precipitate, fusible on being strongly heated; dried in the water-bath it gave the following analytical result:—

Substance, 1.207 grms.; magnesia, 0.090 grm.

	Calculated.		Found.
C ₁₆	192
H ₂₉	29
Mg	12	4.53	4.48
O ₂	32
	265

Besides forming salts, this acid manifests activity in other directions. Its relations with alcohol have been noted and are very remarkable.

This silk-like substance is permanent, and has the power of staining paper. In fact a qualitative test for aldepalmitic acid may consist in getting this stain, which can be produced by very minute quantities of it. I have to notice next a beautiful experiment by Dr. Johnstone. That gentleman had the audacity to attack the butter itself with absolute alcohol, without going through the formality of a preliminary saponification. The details of this experiment he will himself publish shortly. But here are the products. This compound has been dried in the bath, and has lost about two-thirds of its weight; and the substances which I hold in my hand is aldepalmitate of glycerin united with alcohol, really a consolidate, I think. This is evidently one of the aldepalmitic consolidates with alcohol.

I believe that this acid is destined to play a very important part in animal and vegetable chemistry, in the chemistry of nutrition; and I mean to devote much attention to the investigation of its chemical history. What I have already done must be regarded as merely preliminary groundwork.

DISCUSSION.

Mr. OTTO HEHNER wished to ask the author whether, since the subject of his paper was last brought forward, he had or had not estimated the iodine absorption of the body under notice. That absorption ought, as he had before remarked, to be a considerable one, and should set at rest the question as to whether this acid was or was not of the constitution which Mr. Wanklyn supposed. With regard to the author's statements as to the alcohol solidifying powers of his so-called aldepalmitic acid, he would point out that it was well known that a very small quantity of any solid fatty acid of high atomic weight was capable of solidifying a comparatively large quantity of alcohol. A very small portion of wax, for instance, would solidify many times its weight of alcohol. He had recently experimented in that way with stearic acid, and found that one part of it could comfortably solidify five parts of alcohol, which was the proportion which Mr. Wanklyn had stated to be characteristic of his compound. He would repeat that he would like to be informed as to the precise iodine equivalent of this acid, for that would convey more information as to its constitution than the preparation of any number of interesting salts of the compound.

Dr. C. R. ALDER WRIGHT was still somewhat at a loss to know what Mr. Wanklyn meant by the term aldepalmitic acid. If it partook at all of the nature of aldehyde, what were the functions of the oxygen groups in it? If it were an ordinary fatty acid it would be represented by some such formula as—

wherein one oxygen atom was doubly linked on to a carbon atom and the other present as hydroxyl. He would like to know how Mr. Wanklyn imagined that the two oxygen atoms were connected with the carbon atoms in his aldehydic acid.

MR. A. P. HOSKINS wished to have some more definite information as to the character and appearance of the stains produced on filter-paper by the aldehydic acid combined with alcohol, as he had understood Mr. Wanklyn to say that those stains might be used as a test of the presence of the acid.

MR. WATSON SMITH asked whether Mr. Wanklyn considered that the "solidification of alcohol by aldehydic acid" was a semi-combination similar in character to that in the case of water of crystallisation? Also, did he suggest that aldehydic acid was a weaker acid than palmitic acid, and that the glycerol present being too small in quantity for the formation of a possible triglyceride, that it acted with the aldehydic acid to form the kind of semi-compound with alcohol just referred to, in which the glycerol also acted as if glycerol of solidification (if not of crystallisation)? Hence, would Mr. Wanklyn consider that butter, as regarded the aldehydic glycerol compound, was of such a character? If so, it might afford some explanation of the higher degree of assimilability by the digestive organs possessed by it than was the case with ordinary oils and fats of the triglyceride order. These did not suit a great many stomachs, whereas butter was regarded as a general article of food, and was jealously guarded from adulteration by such foreign fats, &c. The stomach, in the case of butter fat, adopting Mr. Wanklyn's results, would have to deal with a more unstable compound than a true fat, and so have less difficulty in disposing of it by the aid of the digestive functions.

MR. WANKLYN, in reply, said that as to the theory of the constitution of the compound he had formed no opinion, and the details he had given were simply the results of his experiments. In naming the acid he had been guided by the fact that it contained a smaller percentage of hydrogen than palmitic acid. That fact was brought out by the analysis. The hydrogen was eight-tenths per cent. too low, and the equivalent of the acid when he determined it turned out to be lower than that of palmitic acid. When he had the facts fully before him, he would form a theory, but not till then. That was the course that he had taken many years ago in a somewhat similar case. He was asked whether he had determined the iodine absorption of this body. He had not done so. He did not expect that there would be any. He had, however, commenced limited oxidation experiments on it, and had found that it was not readily attacked by oxidising agents. He regarded it as one of the permanent acids, and after the experience he had had during 30 years he was not staggered to find that it was apparently an unsaturated compound. The solidification of alcohol had been referred to by one speaker. Under that term he included a very great deal. If one mixed one part of aldehydic acid with five times its weight of alcohol and warmed the mixture, the acid dissolved, but on cooling the whole mass solidified, provided there were not more than five of alcohol to one of the acid. If there were much more, some of the liquid would run away. If one then put the semi-solid mass on filter-paper and pressed it, the mechanically held alcohol was absorbed, and there remained the chemically combined body, and that chemically combined body contained nearly as much alcohol as the aldehydic acid taken. He had made a parallel experiment with palmitic acid, and under the same circumstances there was hardly any retention of alcohol by the palmitic acid. That was a hard fact, and was to his mind absolutely decisive as to the existence of this peculiar acid. With regard to the salts mentioned, he had prepared them carefully, and believed that they were in a state of tolerable purity. As to the nature of butter, he believed, judging from the facts that had come before him, and last of all from the interesting observations made by Dr. Johnstone, that butter was an exceedingly alterable fat, more so than any of the other fats. He believed that in butter they had not an ordinary glyceride, but what he would prefer to call a consolidate, in

which the glycerin and the acid remained side by side in union. Further experience might lead him to discard that view, but at present it was the only conclusion he could come to. With regard to the stains, Mr. Watson Smith had some filter-paper stained by the acid more than a month ago. If Mr. Smith would exhibit them it would be seen that the stains were of a silvery white character.

DR. WRIGHT asked whether Mr. Wanklyn regarded his aldehydic acid as an acid of the acrylic series, of a formula such as he had already put on the blackboard.

MR. WANKLYN replied that it was of that formula, but utterly different in composition. The hydrocarbon group in it was deficient in hydrogen, but he did not think that that necessarily made the acid unstable. It might be built up in a great many ways. The common hydrocarbons should be $C_{15}H_{32}$, but if it were $C_{15}H_{29}$ it was not necessarily unstable. In fact, he regarded this as an extremely stable acid.

DR. WRIGHT said that that being so, he was at a loss to see why Mr. Wanklyn should use the prefix "alde."

MR. WANKLYN said that it was because he was an old chemist, and remembered the history of aldehyde. That body was so named because it contained less hydrogen than alcohol and so he had named his product aldehydic acid because it contained less hydrogen than palmitic acid.

DR. WRIGHT said that in that case it ought to be called dehydroaldehydic acid. If aldehyde meant alcohol minus hydrogen, then aldehydic acid must mean alcohol minus palmitic acid.

MR. WANKLYN replied that he considered that that would be clumsy nomenclature, and he preferred the name he had adopted.

MR. A. NORMAN TATE IN THE CHAIR.

THE USE OF SULPHYDRATE OF CALCIUM IN THE MANUFACTURE OF ALKALI AND BY-PRODUCTS BY HADDOCK AND LEITH'S PROCESS.

BY J. LEITH.

THE process which I have the honour to bring before you this evening has been protected in England and abroad by Mr. A. G. Haddock and myself.

It has for its object the manufacture of alkaline salts, and more especially sodium carbonate, and useful by-products, without the production of offensive waste.

The process as now worked out is simplicity itself, and although it is 15 or 16 years since I first turned my attention in its direction, owing to having accidentally got hold of a process proposed by the late Mr. Arrot, of Liverpool, it has only been arrived at step by step, and it is owing to Mr. Haddock's valuable assistance and co-operation that it has been completed so far as it is, or at all.

As you are all aware, the principal methods by which soda is at present made are two, viz., the time-honoured Leblanc, named after its inventor, and its more recent and successful rival the ammonia process. With the details of these processes by which practically the whole of the soda in this country is being produced, you are doubtless familiar.

Besides these, at least two or three others have been proposed, each having some excellent features, but all failing owing to unforeseen difficulties.

Let us first glance, as briefly as possible, at some of the merits and demerits of these several processes, especially as two of them to some extent led up to the Haddock and Leith process.

First in point of time came the Leblanc process, which has held its own for the last 100 years; and indeed, during the greater part of that time, it has had no serious rival. It is, in my opinion, still the best process for the manufacture of caustic soda, and at present about the only practical one for bleaching powder, as it yields the whole of the hydrochloric acid obtainable from salt, and for this reason will continue to be valuable for some time to come, although it is quite unable to compete with the ammonia process for the production of carbonate of soda.

A great drawback to the Leblanc process for many years has been the production by it of a large amount of offensive material, consisting of impure calcium sulphide, commonly known as vat waste. This waste has been a veritable *bête noir*. Its removal has always been a matter of great expense, and in thickly-populated districts such as Lancashire it is most difficult to get convenient ground to deposit it, owing to the continual evolution from it of sulphuretted hydrogen.

This nuisance has to a very great extent been overcome by the Chance-Clans process for eliminating the sulphuretted hydrogen by means of carbonic acid gas. But the bulk and weight of the waste is still further increased by this treatment, entailing yet greater expense for removal and depositing.

The ammonia process, which works directly from salt, produces carbonate of soda at a price which places the Leblanc process at a disadvantage of nearly 100 per cent., so that competition is out of the question, but has the great drawback of losing all the chlorine of the salt as a waste product in the form of calcium chloride. Until this chlorine is obtained in an available form, the process cannot be looked upon as perfect. It loses also one-third or more of the total salt operated on.

Another method I mentioned as proposed by Mr. Arrot, and which I here call the direct sulphide process, has the advantage that little waste is formed, and that the chlorine of the salt is obtained as hydrochloric acid. He proposed in 1859 to carry this on by fusing ordinary sulphate of soda with fine slack, producing sodium sulphide, which on being treated with carbonic acid gas precipitates bicarbonate of soda. This seems very simple, but unfortunately proved unworkable owing to the great destruction of furnace linings and loss of soda, due to incomplete decomposition, and other causes. I understand this process has been improved on lately. But I think it will still be found to have drawbacks. In order to get the sodium sulphide to fuse in the furnace, a considerable quantity of salt has to be added. This is chemically inert, and goes to contaminate the soda, and to render a portion of it valueless. A comparatively weak sulphuretted hydrogen gas will be evolved from the carbonating towers, which will be troublesome to treat satisfactorily for the recovery of sulphur.

Messrs. Simpson and Parnell proposed another method some few years ago. Briefly, it consisted in making salt-cake in the usual way, thereby producing hydrochloric acid,

then decomposing the salt-cake by the Leblanc process, and afterwards using the vat waste produced to distil ammonium chloride, so getting another equivalent of soda direct from salt, as in the ordinary ammonia process. Unfortunately, although this method was tried with every advantage, it failed, owing to the difficulty of getting complete decomposition of the waste by boiling with ammonium chloride. About five years ago, when the process was brought under my notice, I had a series of trials made upon it, all of which led me to think that it would be troublesome to distil satisfactorily with waste. I afterwards made further trials on the waste with sulphuretted hydrogen, which acted very well indeed, and produced strong calcium sulphhydrate, but, as I said, I only got on step by step, and it was not until about 12 months ago that I saw my way to work the gas—as shown in the drawing—through a series of vessels containing waste cream, for the production of calcium sulphhydrate.

A trial of this on a large scale, treating about 50 tons of waste at a time, proved highly successful, and the distillation of ammonium chloride by the calcium sulphhydrate produced was almost perfect.

At this point Mr. Haddock's chemical knowledge came in most valuable, and he at once proposed superseding the distilling operation altogether by using sulphate of soda instead of salt in the carbonating towers, and finally dispensing with the use of ammonia entirely.

Having now briefly reviewed some of the more apparent points of existing processes which are applicable to what I have to say later, I will describe briefly the principle and *modus operandi* of the Haddock and Leith process.

We make sulphate of soda by the usual method, thus obtaining the whole of the chlorine of the salt as hydrochloric acid. We then use about 56 per cent. of the salt-cake for caustic soda, made in the usual way, producing vat waste, which is then used as one of our raw materials for making a solution of calcium sulphhydrate in the following manner:—

The waste is made into a thick cream with about an equal quantity of water. This cream is then blown into egg-ended upright cylinders A, arranged in series. The cylinders I have practically worked with each contain about 12 tons of vat waste. Weak sulphuretted hydrogen from the carbonators, about 30 per cent., is then blown through the vessels, and it is found to be completely absorbed by the waste going into solution, and rendering an equal quantity of sulphur contained in the waste soluble.

To complete an operation takes from four to five hours in each cylinder, rendering the sulphur contained in four vessels (equal to about 50 tons waste) soluble in about 20 hours, or allowing a little time for charging, discharging, and incidental stoppage of gas, say 50 tons of waste would be treated in 24 hours.

There is about 1 per cent. of sulphur still left in the waste out of the 11 to 13 per cent. originally contained in it. One-half to three-quarters of this undissolved sulphur is combined with iron, and cannot possibly be dissolved by sulphuretted hydrogen. This loss, amounting to about 8 per cent. of the total sulphur, occurs in any sulphur-recovery process and is inevitable.

Calcium sulphhydrate liquor containing 14 per cent. soluble sulphur was obtained from these vessels, working with a gas containing 15 per cent. sulphuretted hydrogen, and 3 per cent. carbonic acid. If gas is made containing no carbonic acid there will be no difficulty in obtaining solutions testing 18 per cent. sulphur. Any alkali which has been left in the vat waste goes into solution along with the calcium sulphhydrate, and is recovered as soda.

An equation will best represent what has occurred—

Calcium sulphide in vat waste and sulphuretted hydrogen give calcium sulphhydrate (soluble in water).

When all the available sulphur in the vat waste in the first cylinder in the series is rendered soluble it is disconnected, and the next in series made No. 1, a newly-filled cylinder being placed in connexion last in series. The finished cylinder may then be allowed to stand and settle. This is apparently a somewhat tedious process, and it may

be more desirable to filter off the liquor at once. I regret I have not been able to ascertain exactly what length of time it takes to settle in the large cylinders, but on letting it stand in a glass jar I noticed that several samples took 24 hours; probably it would come down sooner in a tall column, but at all events the sediment is rather light, and if I were erecting plant I would not be disposed to calculate on less than 20 hours settling. The clear liquor should then be run off into settling tanks G, as shown in the drawings, to remove the last traces of any sediment at all likely to discolour the sulphate of lime produced at a later stage. Water should then be added to the residue in the cylinder, the gas again turned on for a few minutes to thoroughly stir the mass and wash out the sulphur liquor entangled with the spent waste. These washings should be taken to make up a fresh batch of waste cream, and the residue, which is now about one-half the bulk of the original waste, being of no further use, should go to the tip.

So far I have only dealt with making the calcium sulphhydrate from alkali waste, that being the article with which we as alkali manufacturers are most concerned; but you will easily understand that it can be made in exactly the same manner from various earths and minerals containing lime. Instead of Leblanc vat waste, an artificially formed sulphide can be used—of barium, strontium, or calcium—by heating the corresponding sulphate with coal in a reducing furnace. Or, lime may be made into a cream and used as the absorbent, and we are thus rendered independent of the Leblanc process, and also obtain a stronger solution of calcium sulphhydrate, and have no sulphur to recover, as all the sulphuretted hydrogen evolved from the carbonating towers is required for another batch, and acts only as a circulating medium for rendering lime soluble. In this case also, the calcium sulphhydrate liquor would require very little settling, lime being altogether rendered soluble by sulphuretted hydrogen.

The next operation consists in dissolving the remaining 14 per cent. of sulphate of soda made. This may preferably be done by a perforated steam pipe which will serve to agitate the liquor and also keep it warm. Heat greatly increases the solubility and prevents crystallisation. The saturated solution so obtained (at about 125° F.) is neutralised by lime, or by some of the mother-liquor from a later operation, and passed into settling tanks M, as shown, to remove iron and any other impurities which might discolour the sulphate of lime formed in the next operation. One gallon of the clear liquor should contain about 5 lb. of sulphate of soda.

Having now obtained clear solutions of sodium sulphate and of calcium sulphhydrate, these are run together into a wooden mixing tank L, provided with an agitator. Decomposition takes place as follows:—

Sodium sulphate and calcium sulphhydrate and water give sodium sulphhydrate and hydrated calcium sulphate.

Hydrated calcium sulphate separates out as a pure white precipitate, and sodium sulphhydrate is formed in solution. The mixture is well agitated and run on to a filter, K, which retains the calcium sulphate, which is washed with water and pressed or otherwise dried for sale, as pearl hardening. The washings are used for dissolving salt cake for another operation.

The sodium sulphate liquor drawn off from the filters contains a little calcium sulphate dissolved in it (about 1 per cent.), and as this, unless removed, would finally be converted into calcium carbonate, and contaminate the soda, the liquor is run into a mixing tank E, as shown, a little of the mother liquor from the bicarbonate of soda added, and the solution passed through the settling tanks F, as shown, where the calcium salt quickly settles as carbonate.

The clear sulphhydrate of soda liquor is now placed in sodelays or other ordinary carbonating towers H, and lime-kiln gas (as free as practicable from oxygen) pumped through.

Decomposition takes place as follows:—

Sodium sulphhydrate and lime-kiln gas and water give sodium bicarbonate and sulphuretted hydrogen and nitrogen.

The blowing is continued until the sulphur is almost completely eliminated (down to about 1 per cent.) and the alkali in solution will fall to an amount equal to about 3½ per cent. sodium oxide, the remainder separating as solid

bicarbonate of soda. The sulphuretted hydrogen evolved will be mixed with the nitrogen of the kiln gas, but if passed through a column of about 60 ft. of liquor will be free from carbonic acid, and will contain about 30 per cent. of sulphuretted hydrogen. If Leblanc vat waste is used to make the sulphhydrate, about one-half of the gas evolved from the carbonating towers will require to be blown through the waste cream. The other half goes direct to the gas-holder for subsequent combustion and recovery of sulphur.

When the decomposition in the carbonating towers is completed, the contents are blown on a filter D to separate the solid soda bicarbonate, which is freed from mother-liquor as perfectly as practicable, say by a centrifugal machine or vacuum filter, and roasted to soda ash.

The bicarbonate is very pure, as may be seen from the samples which have been made in the manner described. It requires no washing to yield an ash testing 58 per cent. Na_2O .

The filter liquor containing sodium bicarbonate, some sodium sulphate (which was formed in precipitating the small quantity of calcium sulphate in the sodium sulphhydrate liquor) and a little sodium sulphide, may now be concentrated either to obtain soda crystals, for which it is very suitable, or to a strength equal to about 14 per cent. Na_2O , when it is placed in the carbonating towers again and blown with kiln gas until the alkali in solution falls to 3½ per cent. Na_2O . Three-fourths of the remaining alkali will thus separate as solid bicarbonate, and the final mother-liquor is used for neutralising salt-cake solution, and for precipitating dissolved calcium sulphate as described.

Various impurities, such as salt, from the salt-cake will gradually accumulate in the mother-liquor, and after going two or three times round the cycle it will be advisable to boil it down to complete dryness, and sell as 48 per cent. ash.

If the liquor in the carbonating towers is kept at a temperature of about 140° F., the absorption of the carbonic acid gas is more rapid, and the bicarbonate is denser and more easily separated from the mother-liquor. This, I think, is due to that temperature being about the critical point of formation and decomposition of bicarbonate, and that it keeps splitting up into neutral carbonate and carbonic acid gas in atomic form, and reforming. This may, or may not be the correct explanation, but we have observed that the decomposition is quicker at the temperature named.

The manipulation of the various solids, liquids, and gases will perhaps be more clearly followed from the sketch of the plant before you. I have placed all the various vessels in a line for the better exhibition of them, but you will easily understand that they may be placed in any convenient position for actual work.

Having described the working of the process, I will now enumerate the raw materials and the finished products, giving quantities of each.

The raw materials required are salt and sulphuric acid (producing of course salt-cake and hydrochloric acid), limestone and coke (producing CO_2), and Leblanc vat waste (producing calcium sulphhydrate).

From these materials we obtain caustic soda, bleaching powder, sodium carbonate (as ash and crystals), calcium sulphate, lime and sulphur.

As we are all familiar with the manufacture of caustic soda and bleaching powder, I need not further mention them, but deal with the soda ash and by-products only. For every ton of soda ash manufactured we require:—Salt-cake, 28 cwt.; limestone, 22 cwt.; coke 3½ cwt.; Leblanc vat waste 60 cwt.; and of course fuel, about two to three tons. From these quantities we obtain soda ash, 20 cwt.; sulphate of lime, 30 to 34 cwt.; sulphur, 5 cwt.; and lime, 15 cwt.

	£ s. .
Cost of making 28 cwt. salt-cake and its hydrochloric acid at 35s. per ton salt-cake,	2 9 0
" making calcium sulphhydrate from waste,	0 2 6
" fuel, 2½ tons at 7s.	0 17 6
" limestone and coke,	0 8 0
" wages,	1 2 6
" Packages,	1 2 6
Total cost for materials and labour,	6 2 0

Producing 1 ton soda ash 58 per cent. at 13s. 8d. per unit,	6 13 0
" 1 ton 12 cwt. pearl hardening at 2l. per ton,	3 4 0
" 5 cwt. sulphur at 4l. 15s. per ton,	1 3 9
" 15 cwt. lime at 12s. per ton,	0 9 0
" 48 cwt. hydrochloric acid at 6d. per cwt.,	1 4 0
Value of products,	12 13 9
Less 3½ per cent.,	0 8 9
	12 5 0

To the above account of cost must, of course, be added depreciation, f. o. b. expenses, &c. Probably about 2s. should be deducted, on the other hand, for discount on raw materials.

It has been mentioned, as a drawback to our process, that we make a very large quantity of hydrated calcium sulphate, or pearl hardening, and as the market for this is somewhat limited, that it would be difficult to dispose of all we make at the market price of this material, viz. 3l. 5s. per ton. I regret at the moment I am unable to state exactly what the consumption of pearl hardening is, but I know it is very considerable, and, like most other things, will increase if the cost decreases. There is, however, another unlimited outlet for this article for dressing calicoes and other piece goods, for which China clay is at present used. As you are aware, the value of good white China clay for this purpose is 35s. per ton ex quay Runcorn. As I have only valued the calcium sulphate at 40s. in the figures I have read, I am no doubt well within the limit of its value. I might just add that there is also a large amount of sulphate of lime used as plaster of Paris. Under these circumstances, I think the disposal of it would be no very difficult matter. In point of colour and cost it will hold its own against any pearl hardening in the market. As we can afford to throw it away, and still have a margin of profit equal to ammonia soda, it can certainly compete with both China clay and plaster of Paris.

I will now proceed to mention some of the advantages our process has over those at present in operation.

In the first instance, as you have seen, it is entirely a wet process. There is no furnacing in connexion with it, except in the final finishing of the soda ash. You are all aware that furnacing operations involve loss of soda, by volatilisation, mechanical carriage, formation of insoluble salts, and incomplete conversion. These various losses amount in the Leblanc process to about 15 per cent. of the total soda.

In our process there are none of these drawbacks; the liquors are well under control during the whole manipulation. They are easily tested and mixed in the proper proportions. Any mistake can be quickly detected by testing and immediately rectified; so that good results are not entirely dependent on the care and intelligence of workmen. We thus get a much larger yield of finished soda. We also get purer liquors, and consequently a purer finished product.

We have no offensive waste material as produced by the Leblanc process. This waste, instead of being a nuisance becomes a source of profit to that patient, long-suffering beast of burden, the alkali manufacturer, by this process, as not only does he recover the sulphur but also utilises the calcium contained in the waste, reducing it to about one-half of its original weight, the remainder being quite innocuous and inoffensive.

The Chance-Claus process recovers the sulphur from the Leblanc waste, as you know, but in a different manner, and with an expenditure of material which we save.

All the carbonic acid gas used in that process to eliminate the sulphur is lost, and also all the calcium of the waste, these uniting together to form a large quantity of carbonate of lime sludge, so increasing the original weight of waste very considerably, instead of decreasing it by about one-half, as we do.

The carbonic acid gas which we use eliminates the sulphur indirectly from the waste, but never comes directly into contact with it. It all goes to unite with soda, and is utilised except inevitable losses in transmission, and reappears in the finished ash.

The calcium united with sulphur in the waste is also rendered soluble and made use of by us as a carrier for sulphuretted hydrogen, and as a reagent for separating the fixed sulphuric radicle from sulphate of soda, replacing it by the displaceable sulphuretted hydrogen, and finally appears in one of the finished products.

The direct sulphide process, which I have already alluded to, also utilises the carbonic acid and the lime from the kiln, but the formation of the sodium sulphide is brought about by a furnacing operation at a high temperature, and it is well known that the conversion is not complete, that there is destructive action on the furnaces: this has been lessened,

is stated, by the addition of salt. But the yield of soda obtained is poor through losses before mentioned as being inseparable from a furnacing operation, and the added salt plays no part in the chemical reaction.

The sulphuretted hydrogen obtained by our process is also stronger, as we have a sulphhydrate containing two equivalents of sulphur instead of a sulphide with one equivalent, the amount of diluent nitrogen being practically the same. Our gas is consequently more easily treated for sulphur recovery.

We claim advantages over the ammonia-soda method in that we use no expensive carrier, and, having no ammonia, we are free of its expense and losses. We have no distillations to perform to render our carrier re-available, and save on this account a large amount of fuel. We also obtain the chlorine of the salt as hydrochloric acid, and can thus make bleaching powder and other chlorine compounds, which has not yet been commercially accomplished by that process.

We first use the carbonic acid gas to produce bicarbonate of soda in the carbonators, and I would ask you to notice particularly that here we differ from the ordinary ammonia-soda process, inasmuch as we get the whole of the solution of sodium sulphhydrate as bicarbonate quite free from contamination with ammonia and salt; it then only wants drying to be ready for the market as anhydrous or soda ash, whereas an ammoniacal solution only yields about two-thirds of the salt as bicarbonate, and even that is contaminated with $1\frac{1}{2}$ to 2 per cent. of ammonia, besides salt. The salt has to be washed out and carries with it a considerable quantity of the bicarbonate, which is returned to the still with ammonium chloride, and finally passes down the sewer. After all this is done the remaining bicarbonate still contains $\frac{1}{2}$ per cent. NH_3 , which has to be recovered by a drying process, which is perhaps one of the most difficult and expensive operations in the whole cycle. Then our sulphuretted hydrogen, instead of idly passing on from the carbonators to the gasometers, is made to perform a useful operation in the journey and produce calcium sulphhydrate for future use. It is true this throws a little extra pressure on the blowing engine, but this never exceeds 15 to 20 lb. on the square inch. Most of you know the cost of working at this extra pressure is very little compared to blowing steam direct into a column of liquor for distilling. I may

say that I doubt whether this extra pressure is a cost at all, as it so improves the absorption of carbonic acid in the carbonators that it seemed to me, during the trial I had, that it was a decided gain.

I will now conclude this paper by only one or two further remarks.

1. This process wants no great outlay of money for plant, and does not in any way upset an ordinary Leblanc works. Anyone having a Chance plant wants nothing more than a few Solvay towers and old boiler shells for settling tanks to enable him to enter into competition with ammonia soda, and win the race even without counting his profits on bleach.

2. The reactions are brought about easily. There is no long-continued waiting on gases or solids to perform their work. The first and fundamental part of the process, making calcium sulphhydrate, goes on just as surely as melting snow in hot water. The second, precipitating calcium sulphate from the liquor, takes place within two or three minutes from mixing. The third, precipitating the bicarbonate, goes on rapidly and smoothly, even more so than working with ammonia and salt, I think. There are no expensive materials to be lost by evaporation or otherwise. There is no severe action on the vessels employed, so far as I have seen. As all the operations are performed wet and cold, except a little evaporation of liquors and bicarbonate drying, I think the wear and tear on plant will be reduced to a minimum.

3. There are none of the usual engineering difficulties surrounding the process; anyone with ordinary intelligence may erect the plant, and depend on its working satisfactorily. All that is necessary is to select a piece of ground where good foundations can be got for the carbonating towers B. You are aware that the difficulty to get good ground for erecting ammonia-soda works is very great, as a supply of brine must be had, and unfortunately that very flow of brine is liable to undermine the works, and keeps one in dread of the whole thing coming down like a pack of cards any day. That process also wants an unlimited supply of cold water, which is not always available in a convenient position for the best ground to be selected. This large supply of cooling water, and the expense of pumping it, is quite unnecessary in our process.

One ton of 58 per cent. carbonated ash requires:—

	Gallons.		
Calcium sulphhydrate at 46 per cent. sulphur	865		
Sodium sulphate solution at 50 per cent.	614		
	1,479	Yields calcium sulphate	118
Water solidified with calcium sulphate	77		3,676
Sodium sulphhydrate containing soluble U.S.	1,102		
Sodium bicarbonate (mother-liquor)	86	Calcium sulphate	81
Sodium sulphhydrate for carbonating with kiln gas	1,488	118.	118.
Water solidified with bicarbonate 24 gallons	88	Yields 2,231 bicarbonate or 1,407 ash 58 per cent.	
Mother-liquor left in bicarbonate 64 gallons	1,400		
	1,650		
Liquor to evaporate from 3-4 per cent. Na O to 11 per cent.	350	" 1,614 bicarbonate or 641 "	
Sodium sulphhydrate for carbonating with kiln gas	40		17
Water solidified with bicarbonate 44 gallons	310		
Mother-liquor left in bicarbonate 20 gallons	86		
Total for removing calcium sulphate above	224		184
Evaporated for crystals			2,210

50% A per cent. Precipitates in first carbonating operation.

COST OF RAW MATERIALS FOR 1 TON ASH AND BY-PRODUCTS.

DISCUSSION.

The CHAIRMAN said that the paper was an important one and of very great interest to those engaged in the alkali manufacture, and could be well discussed, first as regards the general chemistry of the process, respecting which there would probably not be much difference of opinion; next, the practicability of carrying out the chemical reactions on a manufacturing scale; further, whether the manufacturing operation could be made a monetary success; and, lastly, how far the process could be grafted on to existing processes or how worked as quite an independent operation.

Dr. S. G. RAWSON thought that much too high a price was allowed for the sulphate of lime obtained in the new process. In a works in which he had been interested at one time at St. Helens, they had prepared this substance at his suggestion by mixing together the waste liquors from the Weldon and wet copper extraction process. The resulting product, which was contaminated with a little iron mechanically carried down, was washed with the dilute hydrochloric acid from the condensing tower attached to the copper plant. All these raw materials, therefore, were waste products and were being run away in immense quantities, and the only expense incurred in the formation of the sulphate was in running together and mixing the solutions and then washing the precipitate. It would easily be seen how small this was, and yet so nominal was the price of the sulphate that with all these primary advantages no market could be found for it in quantity. Still less would this be the case with the enormous production which a general adoption of the process described in the paper would entail. Mr. Leith stated that the pearl hardening was used both for sizing paper and calicoes, though the least trace of sulphide left behind in it would spoil it for these purposes, and that it could also be utilised in the manufacture of plaster of Paris. Had this latter outlet actually been tried in practice, or was it only an hypothesis? He himself had

attempted to burn it for this very purpose, but, owing perhaps to the semi-crystalline condition in which the sulphate was precipitated, the experiments had always been failures in his hands. The plaster always remained friable instead of setting hard when mixed with water. He did not think that the calcium sulphate should be looked upon as a source of revenue at all; anyhow it would be safer not to do so for the present.

Dr. F. HURTER said that in discussing the process it would be convenient to do as the Chairman had suggested, and to take the chemical reactions first. There would not be many chemists who would find fault with the process from that point of view. The process of Messrs. Haddock and Leith was one of those which, as Mr. Leith had expressed himself, attempted to remove the sulphur from the sulphate of soda by means of lime in the wet way, and was perhaps the most ingenious of them. Many chemists had attempted to causticise sulphate of soda directly by lime, when sulphate of lime was expected to result; but these processes failed owing to very incomplete reaction. Two years ago the Society had before them another process of similar character, the one invented by Mr. Staveley. In that process a solution of sulphate of soda was treated with lime and phenol, the latter substance bringing the lime into solution as phenolate of lime, and the phenolate of lime decomposed the sulphate of soda, producing sulphate of lime and phenolate of soda, which in its turn was decomposed by carbonic acid.

In the process just described by Mr. Leith calcium sulphhydrate was the alkaline lime salt about to be used to decompose the sulphate of soda. The only question arising was how far was the decomposition complete, how great was the solubility of sulphate of lime in sodium sulphhydrate solution? That would no doubt depend greatly upon the concentration of this solution, the more water it contained the more sulphate of lime would be dissolved. He would

like to have some information as to how far the reaction between calcium sulphhydrate and sulphate of soda was complete.

Then the sulphhydrate of soda was to be treated with carbonic acid gas, to convert it into bicarbonate of soda and sulphuretted hydrogen. Here again the question arose, to what extent could the sulphuretted hydrogen be turned out; could they remove the whole of the sulphur from the solution, or how much sulphide would be left? From investigations which had been made, it was known that sulphhydrate of sodium was not as easily decomposed by carbonic acid as sulphhydrate of calcium.

Looking at Mr. Leith's figures he found that 15 cwt. of lime were produced per ton of 58 per cent. ash, and from this he gathered that Messrs. Leith and Haddock expected to have a poor absorption of carbonic acid.

By this process of carbonating they would have a certain amount of bicarbonate of soda produced, and the question now was, what would become of the free sulphur which was originally contained in the waste, and which passed into solution as polysulphide? That quantity was usually sufficiently large to make him think that the ash made from this bicarbonate would not be 58 per cent. ash at all, but would be much weaker, owing also to the lime precipitated from any sulphate of lime.

Having produced a bicarbonate, they had left a solution still containing bicarbonate of soda, also any sulphate of soda due to incomplete decomposition, and also the common salt contained in the salt-cake. This solution must be boiled down to make soda ash also, and this would not yield soda ash of 58 per cent. According to Mr. Leith the calcium sulphhydrate solution contained 16 per cent. of sulphur. He did not know what strength of sulphuretted hydrogen gas Mr. Leith would have at his disposal, but such as was obtained in the Chance process would hardly yield a solution so rich in sulphur, but the solution would contain only about 12 to 13 per cent. of sulphur. Without touching this point too closely he could only say that, having been allowed to see Mr. Leith's test sheets, he did not think that 16 per cent. of sulphur would be obtained regularly. As far as he could remember the highest percentage had been 16, and more often less, so that the amount of water which had to be evaporated was very considerable.

As far as the reactions did go, they no doubt took place as Mr. Leith had stated.

Looking at the practical aspect of the process, it struck him on looking over the profits to be made by the new process, that not only must manufacturers stop that stupid old Leblanc process, which only realised 2*l.* per ton of ash, but even Brunner, Mond, and Co. must not look to any more of their splendid dividends, particularly when they remembered Mr. Leith's warning about the liability of the works to tumble down any moment; they must all of them immediately adopt that beautiful process of Mr. Leith which brings 4*l.* 4*s.* per ton of ash profit, and if Messrs. Brunner, Mond, and Co. can pay handsome dividends on a profit of 3*l.* 6*s.*, what would Messrs. Haddock and Leith be likely to do with the 4*l.* 4*s.*?

He wished to know with how many tons of ash these figures had actually been obtained? He was afraid the calculations were more theoretical than practical. Thus for instance at the top of the list the Leblanc process was charged with 2*l.* 16*s.* for salt-cake whilst the Haddock and Leith process was charged with only 2*l.* 9*s.*, a difference of nearly 11 per cent.; that meant no loss of salt-cake of any kind. Looking lower down they found a credit to Leblanc process for hydrochloric acid of 1*l.* 6*s.* and one to the Leith and Haddock process of 1*l.* 4*s.*. How was it that the salt-cake used in the Leith and Haddock process produced more hydrochloric acid than the salt-cake used in the Leblanc process? Then again he found that 28 cwt. of ordinary salt-cake would produce theoretically exactly the 32 cwt. of sulphate of lime credited to the Haddock and Leith process. As he had stated before, these calculations were more theoretical than the results of practical working, and the whole process seemed to him to turn really upon the value of the pearl hardening. Taking the 4*l.* 4*s.* from the 6*l.* 4*s.*, there is left 2*l.* 19*s.*, which is only a trifle more than the profit shown for the Leblanc process. But as Mr. Leith had

pointed out, his process depended upon the Leblanc process, and only about half the ash would be made by his own process, and therefore it was necessary to average the two profits whatever they might be.

In the Leblanc process carbonate of soda was at once obtained from sulphate of soda by heating it with limestone and slack, and the fuel used at the same time evaporated the resulting solution of carbonate of soda.

In the Leith and Haddock process the limestone had to be decomposed in a lime kiln, the carbonic acid had then to be pumped, at great cost, to the soda, and the sulphur had to be pumped to the lime. That operation, he was satisfied, would be very costly. Mr. Leith seemed to make very little of the additional pressure which he had to employ to force the sulphuretted hydrogen into the lime. In Widnes great trouble had been experienced with taps, and it was difficult to prevent them leaking and creating a nuisance. They were working generally under 40 lb. pressure. He was afraid that when working under 60 lb. pressure the difficulty would be very greatly increased.

The Leblanc process produced a soda solution containing about 200 grms. per litre of soda, and this was evaporated with waste heat.

The Haddock and Leith process produced a solution of only 70 to 100 grms. per litre, according to the strength of the sulphhydrate of calcium, and would require special fuel for evaporating this weak solution. He was afraid it would be weaker still, for there were so many things to wash. There was the sediment from salt-cake to wash, there was the residue of the vat waste to wash, and the pearl hardening would require considerable washing. He doubted whether all these washings could be used in the process, and whether a great deal of this wash water would not require evaporation also.

Then the Leblanc process produced salts containing 48 per cent. of soda, which had to be calcined, while a great deal of the soda in the Leith and Haddock process was obtained as a bicarbonate precipitate of only 28 per cent. soda. This also required calcination, and was known to be much more costly for finishing than ordinary salts.

He did not see how Mr. Leith could arrive at such enormous profits; they were derived chiefly from the lime and the pearl hardening. The latter would have to be absolutely pure if it must fetch the price stated. He doubted whether it would be absolutely pure—absolutely free from sulphides, iron, &c., and he was very much more afraid that the consumption would be very small. If it had to be thrown away, it would be equally heavy as alkali waste. He did not foresee any great future for the process, and doubted whether it had any advantage over the Leblanc process.

Mr. E. Cuvry drew attention to the fact that according to Mr. Leith's figures 14 per cent. of the alkali produced had to be made by the old process, which would proportionately lessen the profit on the total. With regard to pearl hardening, from the little experience he had he was led to believe that it would be difficult of sale, and that if all the sulphuric acid employed resulted in pearl hardening much of it would have to go to the waste heap.

Dr. T. T. Best remarked that he had tried an experiment regarding the precipitation of calcium sulphate from the sulphhydrate liquor, and found that it gave beautiful long fine needles, only slightly coloured; they were quite silky and very quickly washed clean. He wished to know what amount of sodium sulphide was contained in the bicarbonate, and what percentage of sulphate this gave on calcining?

Mr. Allen thought there was very little to add to the critical remarks to which Dr. Hunter treated the process in question; but he would emphasise just one point in particular—the loss of alkali caused by the action of the oxygen of the limekiln gases on a solution of sodium sulphhydrate, owing to the formation of hyposulphite, &c. This oxygen is a varying quantity, but should it rise up to 2–3 per cent. it would cause a serious loss of alkali, amounting certainly to 20–25 per cent. of the total. This is of course a point not to be overlooked, especially in a process which claims advantages in the yield of alkali in comparison with the Leblanc process. It is also intended

to add salt-cake to a solution of calcium sulphhydrate, then to allow the whole to settle, draw off the clear liquor, and finally to run the gypsum on to filter-beds. This is an operation which would be accompanied with a considerable escape of sulphuretted hydrogen, and such as would give rise to difficulties in practical working.

Mr. HADDOCK replying, said that as the process had been already fully described as far as Mr. Leith and he could see it, he would not go further. Dr. Rawson had mentioned the expense of making pearl hardening from the waste liquors of chemical works, and the difficulty in selling it. So far they had not been able to make it pay, and they could easily understand why, because a series of operations had to be gone through, and a considerable amount of impurity to be removed to get pearl hardening only. Dr. Hurter had asked how much calcium sulphate solution was contained in the liquid: A sulphate of soda in liquid containing 10 per cent. of soda would dissolve .55 per cent. of $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$. If liquors were taken on the strength of figures in the tables it would amount to 2 per cent. of the total salt-cake used. That is not lost in the first operation with the mother-liquor; in their first operation they take back into the sulphate of soda solution the greater part of this liquor. Dr. Hurter seemed to think that there would be a lot of wash-water. He (Mr. Haddock) failed to see that there was. They had to wash certain sludge from the waste to wash out the calcium sulphhydrate, but this was used to make another batch of vat waste cream. The sulphate of calcium washings were used to dissolve salt-cake. Dr. Hurter seemed to think that they had taken theoretical quantities in their experiments, *e.g.* in the pearl hardening. That was so, calculated as *dry* $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$, but Dr. Hurter had overlooked the fact that pearl hardening as sold contained 20 per cent. to 30 the cent. of water, increasing its bulk by one quarter. If the price of the pearl hardening were knocked off, Dr. Hurter had said that would leave but little extra profit over the Leblanc system. He had knocked off 3*l.* 4*s.*, being the price put down as obtained for the calcium sulphate, but said nothing about packages or labour connected with the finishing of this. If it is to be considered as waste material then the labour connected with it and the packages must be deducted from the cost as given, the two items together amounting to about 1*l.* This would still leave a profit by the Haddock-Leith process under the most unfavourable circumstances of 3*l.* 1*s.* against 3*l.* 6*s.* by the ammonia method, and 2*l.* 4*s.* 4*d.* by the Leblanc.

Mr. Carey thought that the profits should be reckoned as the mean of those of Leblanc and Haddock-Leith, as about one-half of the soda had to be made by the former method in order to get vat waste. This is not so, as the figures given were for making soda ash by the Leblanc method, whereas it was proposed to make no ash by that method, but caustic soda only, for which it is still the best-known process.

Mr. LEITH, in replying, said that as regards Dr. Hurter's question as to the solubility of the calcium sulphate in the sodium sulphhydrate, only $\frac{1}{2}$ per cent. of the former was left in solution, and this could be removed as stated in the paper. The liquors operated upon were brought down to 2.4 per cent., or 1 per cent. lower than stated in the paper, but he was unable to state whether it would be profitable to blow them so long as to reduce them to this percentage. Dr. Hurter had also pointed out that from less salt-cake they produced more hydrochloric acid than in the Leblanc process; there was a slight error here, and the quantity stated should be 46 cwt. instead of 48 cwt. Other speakers had said that they were making use of the Leblanc process in this new method. In answer to this he mentioned particularly in his paper that he had confined himself principally to the treatment of alkali waste, and that he was convinced that at the present moment the Leblanc process was the best for the manufacture of caustic soda. The next point Dr. Hurter had raised referred to the pressure employed in the vessels containing the sulphhydrate. In the process he had described they did not work at anything like the pressure (40 lb.) employed in the Chance process; they had left the pressure behind in the carbonators and only had something like 15 to 20 lb. pressure on the first sulphhydrate vessel.

Mr. Auer had referred to the removal of oxygen from the kiln gases. He (Mr. Leith) had shown that the oxygen must be completely removed; this was an absolute necessity in the working of the process.

In reply to the numerous statements made regarding the saleability of the pearl hardening, any quantity could be sold at 35*s.* per ton, whilst those who had paid close attention to the paper would have noticed that this product might be entirely thrown away, and still the process could compete with the ammonia soda process. Dr. Hurter was quite right in remarking that the sulphhydrate was only 15 per cent., and some of it even less than 10 per cent., but that was when working with the gas obtained in the Parnell-Simpson process. In reply to Dr. Best he did not know how much sulphide was contained in the bicarbonate, but no sulphate of soda was found in the ash, as the carbonic acid driven off from the bicarbonate decomposed the sulphide first, reforming carbonate. The result of the last experiment he (Mr. Leith) made was an ash of 58 per cent. Na_2O , which was very uncommon.

Finally, he would state that the process had only recently been patented, and they had only operated on large samples so far as concerned the carbonating of the sodium sulphhydrate; but the operations with waste were conducted on a large scale, 50 tons being treated at a time.

MR. IVAN LEVENSTEIN IN THE CHAIR.

THE TREATMENT OF SEWAGE.

BY GEORGE E. DAVIS.

WE are met here to-night to consider one of the most important sanitary questions of the day. To those who live in small towns situated upon the banks of some large river, where mills and factories are not so abundant as they are with us, the population scanty, and the towns and villages few and far between, the subject will not be of such pressing importance as it is in this part of Lancashire, but to every member of the population, wherever situate, the rudiments of sewage treatment should be read and understood.

To no portion of the country is the question of sewage treatment of more importance than the watershed of the Irwell. Here we have a small river worked as hard as any river can be, turned in fact by many operations into one of the vilest streams in the world, while those tributaries of the Irwell, *viz.*, the Irk and Medlock are, where they join

the main stream, much more foul in themselves than the sewage of many towns. Part of this foulness arises from manufacturing refuse, and the remainder from sewage. We may pause here to inquire

WHAT IS SEWAGE?

The sewage of non-manufacturing towns is easily contemplated. In some cases the excrementitious products are dissociated from the rainfall, the sewage proper being separately treated, while the rainfall is conducted by a separate system of sewers into the nearest river or water-course. This plan, which has been styled the "Menzies" or "separate system," has not found much favour, chiefly on account of the expense attendant upon a double system of sewers, but there is no doubt it is a good method of dealing with storm-water, which in the ordinary way mixes with the sewage and renders such a bulk difficult of treatment. When the "separate system" is not adopted, sewage and rainfall mix together and forms a liquid of very irregular composition.

It must not be supposed, however, that the liquid running from the rain-water sewers in the separate system is an *aqua pura*. The rain and storm-water is, of course, contaminated with the organic matter from the streets, and with the road detritus which gets washed down after heavy rains.

In addition to the foregoing, the sewage of manufacturing towns often contains much liquid refuse coming from factories, such as dye works, print works, paper mills, tanneries, and chemical works; in fact, the Rivers Pollution Act of 1876 expressly provided that facilities shall be given for manufacturers to use the sewers for the disposal of waste liquors.

Attention has lately been drawn to the provisions of the Public Health Acts Amendment Act of 1890, wherein the introduction of chemical refuse into the sewers is, under certain conditions, forbidden. It is to be hoped that local authorities are not relying on these clauses to sever their connexion from manufacturers' drains, unless they are able to define clearly what the words "chemical refuse" mean. It is probable that those who drafted the Bill had some idea in their own minds of the kind of liquid referred to as "chemical refuse," and if so, it is a pity they did not impart that idea more clearly to those into whose hands the Act would eventually come.

Manufacturing refuse does not always render the sewage more difficult to treat, but when dyes and various colouring matters are thus introduced it is often difficult to secure absolute decoloration of the liquid. In such cases, however, the small traces of colouring matters are of no importance when the effluent is turned into a river, the water of which is not used for domestic purposes, and even in such cases it is exceedingly difficult to obtain evidence as to the effect of such minute proportions upon the health of individuals. We do not object to drink our claret or burgundies because they are coloured, or our soups because they are not water-white.

In the treatment of sewage, each town is a separate problem; I am often amused when reading of the visits of deputations to the Lebanon Sewage Works of Mchona, or elsewhere, as the case may be, to find the opinions expressed, that, as that particular process worked well at Mchona it must answer anywhere and everywhere else.

Neither can I agree with the doctrine of the Local Government Board in laying down a hard and fast rule as to filtration through kind. All circumstances must be taken into account, and local conditions and conveniences must certainly.

We come again to the question, what is sewage? to which a general reply may be given as a water supply that has been polluted by reason of domestic and trade use. Food is boiled, the water thereby becomes charged with organic and mineral matters; garments are washed with soaps and alkali to remove the sordid accumulations; floors are cleaned and drains are disinfected, all adding to the pollution. When we add to this the excrement products, the liquid refuse of certain trades, we have a typical sewage of manufacturing towns.

Let us take the Salford water supply and the Salford sewage as an illustration:—

PARTS PER 100,000.

	Salford Water Supply.	Salford Sewage.
Suspended matters:—		
Mineral	4.47
Organic	7.84
Total	Nil	12.31
Total soluble solids	7.14	137.11
Loss on ignition	4.28	35.71
Total hardness	6.00	23.14
Permanent hardness	5.43	17.85
Temporary "	0.57	5.28
Chlorine	1.25	45.64
Alkalinity (H ₂ SO ₄ neutralised)	Nil	24.89
Free ammonia	0.061	1.17
Albuminoid ammonia	0.005	0.55
Absorbed oxygen	0.06	17.68
Nitrates (calculated as HNO ₃)	0.21	0.11
Soluble iron (as Fe)	0.04	0.21
" lime	0.84	13.21
" magnesium	0.43	3.89

If we reckon the Salford sewage to possess a daily volume of 10 millions of gallons we shall find there have been added, per diem:—

Suspended matters:—	Tons.
Mineral	2.9
Organic	3.5
Total soluble solids	58.0
Total hardness	7.7
Chlorine	19.9
Alkalinity	11.2
Total ammonia	0.9
Iron	0.4
Lime	5.6
Soluble organic matter (loss on ignition)	13.5

This gives us a very good idea of the quantities that have to be dealt with in a place such as Salford. The mineral suspended matters amounting to over 2 tons daily cannot be considered inimical to the public health, but the 3½ tons of suspended organic matters soon enter into putrefactive decomposition and become a nuisance.

The soluble matters added to the water daily and forming sewage amounts to no less than 58 tons. Of these, the mineral constituents can scarcely be considered injurious. The soluble organic matter, however, has to be reckoned with as being a highly putrescible impurity; it amounts to no less than 13½ tons daily, and contains in its original state nearly 1 ton of nitrogen, reckoned as ammonia. These complex nitrogenous substances are easily decomposed, forming much simpler compounds. They are acted upon by lime and other alkalis with the formation of substances more or less pungent in odour, and if allowed to enter into putrefactive decomposition, sulphuretted products are formed from the sulphur they contain, causing very unpleasant smells.

Fortunately these complex compounds form insoluble substances with many metallic bodies, and are precipitated from the solution in combination with them, and a variety of substances for the purification of sewerage has been proposed and re-proposed since the days when sewage first came into legal existence.

I should like to point out here that caustic alkalis and alkaline earths, such as lime, act very energetically upon

the soluble organic matters of sewage, and produce results which shall be shown to you later on.

To those who know the Irwell, Irk, Medlock, and Roch as they are, any argument insisting upon the purification of sewage will be superfluous, but I have already pointed out how readily the organic matter of sewage mud will enter into putrefactive decomposition.

If the suspended matters of sewage would quickly deposit themselves so that they might be retained, while a clear effluent passed on, there would be but little difficulty in improving the sightliness of the streams into which sewage now runs. The complete clarification of sewage by subsidence alone is, however, impossible, on account of the glutinous and albuminous nature of the intermedium; it is on this account also that continuous filtration, say through sand, is impossible, such a filter soon becomes clogged with fungoid or algoid growths, and ceases to act altogether.

But if the suspended matters are entirely removed, we have in the bulk of 10,000,000 of gallons of sewage $13\frac{1}{2}$ tons of soluble organic matter still to deal with. This must not be forgotten. I do not wish you to infer that it is necessary by any means to totally remove this soluble organic matter, but it is certainly necessary to alter its constitution, so as to render it as little capable of further decomposition as possible. I have already alluded to the albuminous nature of these $13\frac{1}{2}$ tons of soluble organic matter. Albuminous substances are characterised by their complex constitution, their easy decomposition, and their readiness to enter into putrefaction, by reason of which the nitrogen they contain goes chiefly to form ammonia, and the sulphur to produce sulphuretted hydrogen, so that the albumen molecule is completely broken up and entirely new substances produced, which are not so liable to further change.

The albumen molecule can also be split up by many chemical substances, and in most instances without the disgusting odour which manifests itself during the putrefactive process.

The soluble organic matter of such a sewage as Salford is slowly oxidised by contact with the atmosphere. This sewage requires $7\frac{3}{4}$ tons of oxygen daily to carry the oxidation to what I should call a safe point, or in other words, would abstract the oxygen completely from no less than 1,000,000 cubic feet of air daily.

When crude sewage is allowed to pass into a river, many changes too numerous to mention take place. When the rain-water also enters it contributes no little towards the general impurity, the road-detritus gets mixed up with organic matter and forms a silt at the mouth of every river which has large towns upon its banks. We may take the Tyne at Newcastle, the Humber at Hull, the Thames at Gravesend, the Itchen at Southampton, the Medina in the Isle of Wight, and the Mersey at Seacombe, as illustrations of the accumulation of organic matter and mineral substances that are brought down stream.

In the *Archæological Journal* for 1885 Mr. F. C. J. Spurrell gave an excellent account of the alluvial deposits of the lower Thames. He says "the old freshwater bed at what is called the mouth of the Thames had sunk much further below the sea-level than at Richmond by the time the sea had reached the latter spot, and in doing so had afforded room in its bed for successive deposits of mud and refuse." This mud is now dredged or dug up, mixed with carbonate of lime or chalk, and after some further treatment becomes Portland cement, not only in the Thames estuary, but on the banks of the mouths of all the other rivers I have just mentioned.

The following partial analyses will show the composition in silice, alumina, and oxide of iron of ignited alluvium used in the manufacture of Portland cement:—

	a.	b.	c.	Average.
Silica.....	51.6	62.1	56.1	57.6
Alumina	16.7	16.6	16.7	16.6
Oxide of iron ...	8.8	7.5	10.6	8.9

The reason why these analyses are introduced here will be rendered apparent later on.

We may now pass to the

PECUNIARY INDUCEMENTS TO THE TREATMENT OF SEWAGE.

and we shall find that most inventors have had an eye to extracting hidden wealth therefrom. The ammonia and phosphates have been the chief constituents sought to be turned to account, and at first sight it does seem strange that such valuable constituents should be wasted. The nitrogen contents of such a sewage as that of Salford are equal to 3 tons of sulphate of ammonia daily, or more than 20 tons weekly, of a weekly value to-day equal to 220*l.*, or 11,000*l.* yearly, and yet there is no process at present worked that would be able to extract that ammonia economically.

The problem is that of extracting three-quarters of a ton of ammonia from 50,000 tons of water, which it will be admitted is no easy task. It must not be forgotten that the ammonia principally resides in the soluble portion of the sewage, and this is in a great measure overlooked by those who have attempted to make a profit during sewage treatment.

We now come to the sludge. Some inventors tell us there is a mine of wealth in this—for use as a manure; if this be so, why is it that the managers of sewage precipitation works endeavour to produce the least possible quantity? My opinion is that its use as a manure is not a proper use, and that it can be turned to better account. The phosphates, the potash salts, and the organic matter will be best left out of the question, they can only be dealt with by irrigationists, and irrigation is not practical everywhere.

We may now consider some of the various processes that have been put into actual practice for the treatment of sewage, and of them we may first glance at

FILTRATION PROCESSES.

Irrigation is essentially the most rational of all filtration processes. It is a filtration through soil permeated by the roots of plants, and the altered products of the sewage are absorbed thereby. I am not one of those who think that raw sewage should be applied to land, but I do believe that, wherever it is possible, the effluent from a precipitation process should be made to give up its valuable fertilising materials to growing crops, and by this I mean that precipitation should always precede irrigation. The value of sewage as a fertiliser lies in the effluent.

Filtration of sewage through ordinary garden soil, without any previous precipitation, was experimented upon in 1868 by a Mr. Edward Brown, who in a subsequent year attempted to treat the sewage of the workhouse at Slough by his method. I had the privilege of making the chemical tests upon this process, and have no hesitation in saying that it was a process that could not be applied to the sewage of a large place like Salford.

Many experimenters have found that a simple filtration through sand will purify sewage to a very great extent, and the same may be said with reference to the use of iron, carbon, coke, and other materials as the filtering medium. The filtration of raw sewage, however, is attended with many practical difficulties, amongst which the rapid clogging of the filters and the deterioration of the quality of the effluent after a very short time of usage are the most apparent.

Filtration, pure and simple, will only remove the suspended matters; but as in perfectly fresh sewage, more than the moiety of the albuminoids are insoluble, this will at once account for the improvement that takes place by filtration only. But it is difficult to avoid aëration taking place during filtration, and aëration is a wonderful purifying operation. In ordinary filtrations *per descensum* aëration takes place to some extent simultaneously with the retention of the suspended matters.

OXIDATION AND REDUCTION PROCESSES.

come forward next for our consideration; perhaps the least expensive is that of treating the sewage with a current of air.

I have already shown you that the organic matter of the Salford sewage requires the oxygen of at least 1,000,000 cubic feet of air daily. These are theoretical numbers. In practice, judging from other processes with which I am well acquainted, the quantity of air required would be at least 16 times this, and this volume would in the ordinary way have to be forced through a depth of not less than 6 feet of the sewage.

Sixteen millions of cubic feet per diem may roughly be called 700,000 cubic feet per hour, or 11,000 cubic feet per minute, so that by following gas-works practice or blast-furnace practice we may arrive at a very fair idea of the cost of aeration by these or similar means.

There is no doubt aeration is beneficial, and by itself retards putrefaction in a very remarkable manner. The late Dr. Angus Smith, in his last report as inspector under the Rivers Pollution Prevention Act, threw out a suggestion that probably a combination of the lime process with aeration would be the best that could be adopted. The reasons for this conclusion will be given presently.

Another way of aerating sewage would be to run it down a tower packed with suitable material and pass a current of air upwards, but then there would be the whole of the sewage to raise to a high level, the cost of which can be readily calculated. Undoubtedly the most perfect mode of aeration is that you see before you in the model plant now working. There the liquid is at small cost carried up as a spray or rain shower, and the small particles are completely surrounded by the atmosphere which is rushing forward through it.

After the process of oxidising with air we may consider the use of bleaching powder, of which 100 tons would be equal to 8 tons of oxygen, or in other words the Salford sewage would require 96 tons of bleaching powder daily to bring it to the same state of purification as can be accomplished in the laboratory. At its present price, this quantity of bleaching powder would cost over 576*l.*, or over 200,000*l.* yearly.

Manganate of soda, and permanganates have been both proposed and used as oxidants for sewage, but as I am afraid the figures and cost of such, required for *complete* oxidation of the sewage, would be too enormous for contemplation, I forbear to present them to you. Of course I am prepared to be told that there are works wherein manganates are employed, and that the cost is not too excessive, but I may say it is an easy thing to purify the sewage "just a little." This "just a little" has been the bugbear all along the line. Works have been put up, with the best intentions no doubt, but after a year or two the chemicals have been reduced to "just a little," and consequently the soluble impurity has passed away unacted upon. The success of chemical reactions required that certain known quantities of materials shall take part in those reactions, and if those quantities are not present, the reactions will take place only in proportion to the quantities present.

Reduction processes have been but little studied. Electrolysis may be considered as coming under this head, but seeing that so much has been said upon a process of this kind just lately, it would be only a waste of time to recapitulate those remarks here. The rationale of the process does not seem to me to be completely understood as yet.

We must now turn to

PRECIPITATION PROCESSES.

It would be folly to attempt, in the short space of an evening's lecture, to describe all the various processes and chemicals that have been proposed from time to time for the treatment of sewage. The various precipitants require to be added in definite quantity and in proportion to the amount of the impurity present. It is easy to watch the effect of gradually increasing quantities of chemicals upon sewage, by the addition of such substances as sulphate of alumina, or persulphate of iron. Small quantities of persulphate of iron, such as 5 cwt. or 10 cwt. per million gallons, will not have much effect upon the soluble organic matter when over a ton per million gallons is used, the effect is noticeable, but the maximum purifying effect is not reached with even 30 cwt.

No doubt it will be urged that the addition of 30 cwt. of such a substance as sulphate of alumina to the million gallons of a sewage such as Salford, produces a very marked improvement, and hinders the commencement of any putrefactive change, and this is undoubtedly the case. This is also more marked with the persulphate of iron, which acts as an oxidising agent in addition.

The general action of precipitants of a neutral or slightly acid character is to form insoluble precipitates with some of the albuminous constituents of the sewage, and cause their deposition as sludge. It is precisely a similar action to that which takes place when a soluble moriant and a soluble colouring matter are brought together in a suitable intermedium, a reaction so well known in this district amongst the dyeing and printing industries.

What I wish to point out most clearly and definitely is, that the action is a chemical one; it takes place through the intervention of fixed and definite quantities, so that less than the required quantity will not purify, while more than is requisite chemically, though it generally accelerates the action, is wasted.

Many faults can be found with most of the precipitation processes. Of course, if we read the various pamphlets describing these processes, we shall discover that everything goes as gaily as a marriage bell. How is it, then, that some one process or another has not been universally adopted?

The cause is not difficult to discover. In the first case, the cost of chemicals to effect the maximum purification is too great to be borne long. Secondly, the production of sludge and its disposal is no small problem, as on account of its bulk and the large percentage of water it contains it is a very unmanageable product.

Whenever this question crops up at a Government inquiry we are always told that farmers are only too glad to get the sludge as a manure. It is not my intention to dispute this to-night; I often wonder whether the gentlemen responsible for these statements actually believe in the truth of them.

Up to this point I have omitted all mention of the lime process, because, although it is a precipitation process, yet the reaction goes much farther when sufficient lime is applied.

In the report of the late Dr. Angus Smith to the Local Government Board, issued in 1882, he writes:—"In the first proposals for purifying water by Thomas Henry, F.R.S., of Manchester, about a century ago, lime was used, and after precipitation carbonic acid was employed to neutralise any excess. Any excess of carbonic acid over the lime would be an improvement. Free lime in water is a great disadvantage. Indeed we must look carefully to our streams whenever lime is used for precipitation. It is a favourite poison for fish, and I have seen a clean solution from a precipitating tank become suddenly whitish on entering a river of clean water. The process was intended for purifying the river, but it was in reality adding a new poison."

In that report, Dr. Angus Smith further writes:—"Lime does not disinfect in such a way as to prevent putrefaction as long as aeration does, but it clears the liquid more thoroughly, and if the effluent is removed the putrefaction resulting cannot be equal to that which would take place in the aerated sewage after a certain time."

"This seems to lead to another point, namely, it is not best then, to use both processes—the lime and the aeration?"

For some years past we have been endeavouring to bring the late Dr. Angus Smith's ideas to a practical success.

The chief faults of the lime process as at present conducted are, that if only a small quantity of lime be used, say 7 or 8 cwt. per million gallons, the whole of it is seized upon by the free and loosely combined carbonic acid the water contains, and but very little, if any, purification is effected. The precipitate of carbonate of lime perhaps causes a more rapid deposition of the suspended matters present, but here its action ends. Upon the addition of more lime, say to 18 cwt. per million gallons, some of the soluble organic matter is acted upon, a partial resolution of the albumenoids takes place, and insoluble salts of lime are formed as a thick curdling precipitate which settles very readily.

I was anxious to show you the effect of adding 18 cwt. of lime to the million gallons of sewage, and as the remark was made in this room at our last lecture that laboratory experiments were not to be trusted, we place before you the results of the analysis of samples of the Leeds sewage before and after treatment in actual practice:—

Soluble Matter, Parts per 100,000.	Raw Sewage.	After 18 Cwt. Lime.	More Lime.
	<i>a.</i>	<i>b.</i>	<i>c.</i>
Total soluble solids	125.7	135.0	277.8
Loss on ignition	56.4	27.1	25.7
Total hardness.....	27.1	54.0	258.0
Chlorine	13.9	18.7	17.2
Alkalinity (H_2SO_4 neutralised)	31.3	31.4	220.0
Free ammonia	2.8	2.4	2.5
Albuminoid ammonia	0.4	0.26	0.14
Absorbed oxygen	18.0	11.7	4.2

These figures are very instructive; the water in column *b* possessed no greater alkalinity than did the raw sewage; it had a brownish tinge and a very bad odour, much intensified by standing one day in a warm room; the albuminoid ammonia had been reduced from 0.4 parts to 0.26 parts, or 35 per cent. removed. The loss on ignition had been reduced from 56.4 to 27.1, or 52 per cent., while the absorbed oxygen had sunk from 18.0 to 11.7 or 35 per cent.

A further quantity of lime was now added in the laboratory, and after well mixing it was allowed to settle clear. The clear fluid on being analysed gave results shown in column *c*, from which it appears that while the albuminoid ammonia had been reduced from 0.26 to 0.14 or 45 per cent., and the absorbed oxygen from 11.7 to 4.2 or 64 per cent., the loss on ignition had only been reduced from 27.1 to 25.7 or 5 per cent.; evidently the limit of its action upon the non-aluminous matter had been reached. The liquid represented by column *c* possessed a very peculiar odour quite distinct from that of column *b*, and was perfectly clear and water-white. This liquid was blown with air, when it soon lost all its odour, and appeared like an ordinary sample of tap-water. It was, however, highly alkaline, and so would be a very objectionable liquid to enter a stream.

I have now said enough to show you the chief faults of the lime process as it is at present practised. A small quantity of lime simply combines with the carbonic acid, and does not act upon the soluble impurities at all. A little more lime added, we will say, until the effluent commences to show the faintest trace of alkalinity to red litmus paper (say 18 cwt. per million gallons) produces a decided purification; but the highest degree of purification is not reached until at least two tons of lime have been added to the million gallons.

Now, on adding more lime to sewage, we get, of course, more sludge, and where sludge is difficult to dispose of, this is a serious objection to its production, the tendency being to cut down its formation to the lowest possible limit. But if sewage sludge could be turned to profitable account, the more sludge, of course, the more profit.

The effluent from sewage that has been treated by lime possesses a very peculiar and noxious odour, and if sufficient lime has been used to effect the maximum purification it is highly alkaline, is thus extremely poisonous to fish, and on account of its alkalinity soon enters into a putrefactive decomposition of the worst order.

If the foregoing objections could be overcome there is no doubt that all other methods of treating sewage would find in lime a powerful rival, even if it did not supplant them altogether.

We may say at once that we have succeeded in:—

First.—Removing the whole of the insoluble albuminoid.

Second.—Removing 63 per cent. of the soluble albuminoid matter.

Third.—Completely deodorising the effluent.

Fourth.—Restoring the neutrality of the effluent, and

Fifth.—Utilising the sludge at a profit.

The apparatus in which all these wonderful things are done is shown in the model now at work on the table before you. The lime is introduced in two separate portions; in the first mixer about 7 cwt. per million gallons are added which seizes hold of the carbonic acid at once. The mixture then flows into mixing tank No. 2, where a further quantity of about 33 cwt. of lime is added. The limed sewage now flows through a series of subsidence tanks in a constant stream, leaving the last tank, as you will see, a highly alkaline and peculiar smelling liquid. The odour of this liquid is certainly not a pleasant one, and the next step must be to deal with that odour in a satisfactory manner. You will notice, the liquid is perfectly clear, and that it is highly alkaline to the red litmus with which I mix it. The odour of the water at this stage is, no doubt, due to the vapours of several volatile organic compounds of an easily oxidisable nature, or such as are expelled when the partially treated sewage is submitted to aeration. This aeration takes place at the many weirs on the river Irwell, and the odours prevalent about these spots are too well known to require description. What nature does at the weirs, we do here in this aerating chamber.

The sludge produced by the lime remains behind in the subsidence tanks; we will return to it later on. The clear liquid leaves the last tank and passes into the aerating chamber, or rather it should be called the aerating and carbonating chamber. A very thin layer of this odorous and alkaline liquid lies upon the floor of the chamber, and flows over it in a constant stream; during its passage through, it is projected upwards in the form of a rain shower, and, through this rain shower of partially purified sewage, a current of warm air is made to flow, which displaces and oxidises the organic odours, and, further, a current of carbonic acid is also sent through the chamber, which is absorbed by the lime dissolved in the partially purified sewage, forming an insoluble carbonate of lime, thus changing the alkaline character of the sewage to one of neutrality, and bringing the excess of lime into such a form that it can be further utilised.

I must digress a moment here to say a few words respecting the atmosphere of this carbonating chamber. The atmosphere entering consists of a mixture of air and carbonic acid (both warm), or in other words, of carbonic acid, oxygen, and nitrogen. The carbonic acid is absorbed by the lime of the rain shower; some of the oxygen is also absorbed by the soluble organic matter, while the excess of oxygen and nitrogen escapes.

The ammonia of the sewage is, as I have already shown you, the valuable constituent, and when the sewage is strong, ammonia is found in the gases escaping from the aerating chamber. When this occurs it is the easiest thing in the world to collect it. The model before you shows how this can be done. The escaping gases are passed through a scrubber packed with suitable material kept moistened with an acid solution; the acid absorbs the ammonia, and the liquid draining from the scrubber can be readily utilised. I must, however, say that with sewages as weak in ammonia as that of Salford, there are only traces of ammonia to be found in the gases leaving the aerating chamber; but with some sewages, such as that of Aldershot, ammonia readily comes off in paying quantities.

We must now return to the liquid running from the aerating chamber. You will observe that it has a milky appearance. This has been produced by the transformation of the soluble lime into a white insoluble carbonate, and nothing remains now, so far as the sewage is concerned, but to settle out this carbonate of lime and to allow the effluent to flow away—anywhere. It is a neutral liquid, clear, bright, and free from odour, and if exposed to the air for any length of time does not deteriorate in quality. The sample in the bottle before you is the identical one that I showed you on December 3rd in last year.

But I fancy I hear some of you asking: How and whence are the currents of warm air and carbonic acid obtained? For this information we must now follow the sludge.

The sludge produced by the treatment of the sewage with, say 40 cwt. of lime, and deposited from the liquid before its entry into the aerating chamber, is run into a mixing tank at a lower level. The sludge produced by treating the alkaline liquid with carbonic acid and air in the aerating chamber, plus any mud formed in that chamber itself, is also run into the same receptacle.

We may now pause a moment to inquire into the composition of the mud or sludge that has found its way into the mixing tank. It contains free lime, carbonate of lime, organic matter, mineral substances, consisting chiefly of silica, alumina, and oxide of iron, together with a quantity of nitrogenous material that forms and evolves a considerable quantity of ammonia during drying and heating. In other words, it consists of the organic matter of the sewage, the lime that has been used in the precipitation, the road detritus, and the water. Upon drying this sludge, water and ammonia are given off; the residue loses its organic matter during calcination at a red heat, leaving lime or carbonate of lime mixed with the silicate of alumina and oxide of iron of the road detritus.

It is, however, with the *wet* sludge that we have to deal, a sludge containing nearly 90 parts of water in every hundred parts by weight; it must be dried, or semi-dried, before it can be dealt with; and of what use is it when it is dried? Sell it as manure, as we are told they do at Leeds and Bradford, says one; dig it into the land as they do at Birmingham, says another; run it over some low lying land, says a third, as they do in Salford. I have already stated that "its use as a manure is not a proper use, and that it can be turned to better account." It has already been shown to you how the road detritus, and other substances are washed down to the mouths of rivers, from whence they are afterwards dredged. Mixed with chalk, dried, burned, and ground, they become Portland cement. A well-made lime sludge should contain all the elements for the manufacture of Portland cement of good quality, but the success of this manufacture principally depends upon the proper regulation of the materials used in the mixture.

When the slurry is run into the mixing tank from the first and second series of subsidence tanks, it must first be examined chemically and means taken to secure that for every 70 parts of lime present, calculated as carbonate of lime, there shall be also present about 30 parts of silicate of alumina of such a quality as is found in the mud of estuaries. I have examined the aluminosilicates of several lime sludges from sewages and find them to compare with those of cement slurry as follows:—

	Sewage Sludge.			Cement Slurry.		
	a.	b.	c.	d.	e.	f.
Silica	63.0	60.0	57.4	139.9	213.4	20.8
Alumina	30.5	21.3	27.5	12.2	9.7	7.9
Oxide of iron	17.9	12.1	15.3	7.4	5.1	6.2

At this point I am prepared to hear urged the criticism that there is nothing new in the proposal to make cement from sewage sludge, and that it has been attempted over and over again and failed. Just so. When it was first proposed to steam ships to America Dr. Lathrop endeavoured to prove that such a state of things could never come about for a vessel could never carry coals enough to raise the steam, let alone find room for passengers or cargo. When the London Gas Company's Bill was before Parliament in the early days of this century one honourable member indignantly asked a witness, "Do you mean to tell us, sir, that you can get a light without a wick?" and when answered in the affirmative, he replied, "Ah, sir! You try to prove too much." We have heard enough of these things in our day—gas could not be used for cooking yet people cook by it; electricity could not be used for lighting yet the contrary has been proved; people could not possibly talk to each other 100 miles apart, yet it is now done. Inventions seem to have to struggle through four distinct stages: the first or receptive stage; many may be working

at this but only a few are in the running for success; next comes the cold water stage, in which all interested parties use their utmost endeavours to sink the new idea, the vested interest parties look on with fear and trembling, the wiseacres predict nothing but failure, while the man who has turned his thoughts in similar directions feels himself aggrieved, robbed, plundered, and shorn of honour, so that he feels it necessary not to increase his own chances of success but to endeavour as far as possible to pull his neighbour down from the pinnacle upon which he desires to establish himself. The third stage is reached when some one or other of the numerous inventors has achieved success. By steadfast application, by steady and untiring work at the difficulties as they have arisen, he has swept them all away and awaits his reward. So soon as this stage is ended the fourth begins. It frequently commences by a few disappointed patentees announcing the supposed infringement of some pet patent of their own. As a rule such men have a bank balance of the most meagre description, and as they have all to gain and nothing to lose, a law-suit has no terrors for them. Apart from this, the vested interests and the wiseacres have now altered their tone, "no utility," "no utility," is the cry now, while not the smallest noise is made by those who are loud in asserting "there is nothing new in it," "it has been patented over and over again, years and years ago."

We expect this is what many will say when we tell them that we have not only succeeded in purifying sewage by means of lime, but also in making cement from the sludge at a profit. When Weldon brought his chlorine process to perfection he was first told it would not answer, and then when it did answer, that Gossage and not he was the true inventor. When Mond introduced the ammonia-soda process into Cheshire he was first told it could not be done on account of the loss of ammonia; the second opinion was, that it had been tried by many and had been given up, and was moreover "as old as the hills." So all new processes are treated.

We know perfectly well that sewage has been purified by lime before, limed water has been treated with carbonic acid, sewage has been treated with air currents, the air currents have been robbed of their ammonia, and several have tried to make cement out of the sludge. In spite of all this, where is now the works existing wherein the sewage of any town is treated on the lines I have already indicated?

But I have not finished; we are still at the mixing tank. As I have already explained, the mixture is ascertained to contain 70 parts of carbonate of lime to 30 parts of silicate. Ordinary sewage sludge, made with 18 cwt. of lime to the million gallons, I have always found to contain too much silicate, that is to say, too little lime, so that I see no difficulty in properly apportioning it to the needs of any particular district. On the other hand, suppose a very large excess of lime over the silicate has to be used to purify some very foul sewage, field clay, fire clay, or river mud, or crumbled-down shale banks, or even well ground ash-pit clinkers may be employed to bring up the proper proportion of silicate. A few partial analyses of these substances may not be uninteresting here:—

	Field Chyss.			
	a.	b.	c.	d.
Silica	65.6	62.6	67.0	61.4
Alumina	34.5	27.6	17.6	24.0
Oxide of iron	9.6	8.6	9.0	14.0

	Coal Pit Shales.			
	a.	b.	c.	d.
Silica	68.0	47.4	36.4	55.8
Alumina	22.6	20.8	16.5	21.6
Oxide of iron	7.8	0.2	11.4	8.2

	Clinkers.		Fire-clay.	
	a.	b.	a.	b.
Silica	43.4	33.0	46.7	57.2
Alumina.....	29.9	11.7	17.6	28.9
Oxide of iron.....	10.4	8.6	6.0	1.1

The sludge or slurry is then pumped into the drying chamber you see before you; it is a closed chamber, upon the floor of which the sludge lies, and is exposed to the waste heat coming from the cement kiln which is built at one end of it. By the time the kiln has burnt itself out, the sludge has become dry, and forms the next charge. The dried sludge is now packed into the kiln with intermediate layers of coke, the coke is lighted by a fire at the bottom of the kiln, and the charge drawn so soon as the particles commence to frit together. When drawn from the kiln in this state, it is known as "clinker," and, after being ground and sieved, becomes Portland cement.

We must now turn our attention to the course of the gases leaving the fireplace and kiln, as it is from this source we obtain our supply of warm air and carbonic acid gas. The combustion of the coke in the kiln, and also of the organic matter of the sewage sludge, together with that expelled from the carbonate of lime, give all the carbonic acid required, which passes forward into the drying chamber at a red heat. The heat, passing over the surface of the wet sludge, dries it, the vapour passing off mixed with much ammonia or its carbonate. This ammonia is arrested in acidulated water, the gases passing down scrubber through which they pass while still warm into the aerating and carbonating chamber, where they act upon the highly alkaline and partly purified sewage in the manner already described. You will thus notice that the carbonic acid is not sent out of the process; it comes round again and again, so that a fresh supply, such as is yielded by the burning coke in each operation, simply goes to make up the working loss.

The Salford sewage, treated this way, would yield 260 tons of cement per week. Some of you may think this a large quantity, but when I tell you that I used to inspect one works making 1,200 tons a week, and another making nearly three times that quantity, and that there are many others of similar magnitude in this country alone, you will, I imagine, not be frightened at 260 tons per week. Again, if only one-third of a grain of ammonia were extracted from a gallon of each of the ten million gallons of sewage, it would amount to no less than six tons per week, but the cement revenue is quite good enough without that coming from the ammonia.

The weekly cost of carrying out this system night and day, without taking into account interest on capital, depreciation of plant, and other incidental expenses, is, as far as we can estimate, as follows:—

Lime, 140 tons at 10s.....	70
Shale or clay, 70 tons at 5s.....	18
Coke for burning cement, 50 tons at 10s....	25
Labour, 40 men at 25s.....	50
Acid oils and sundries	47
Coals for steam.....	70
Balance, profit.....	365
	<hr/> 645
The revenue being:—	
260 tons cement at 45s.....	585
6 tons sulphate of ammonia at 10l.....	60
	<hr/> 645

Annual balance of revenue over expenditure..... £18,980

As to cost of plant, this cannot be excessive, considering it is only an ordinary cement plant, with carbonating chamber tacked on to the usual precipitation works. But there is this difference, that while a cement maker proper

has to possess boats, and to dredge or dig for his mud, and to get his chalk, it is here pumped into his works ready mixed for him. And again the precipitation department need have no trouble regarding sludge disposal, or the alkalinity of its effluent; both have been well provided for.

ON THE RELATIONSHIP BETWEEN THE COMPOSITION OF GREY CLOTH AND ITS LIABILITY TO MILDEW.

BY ROWLAND WILLIAMS, F.L.C., F.C.S.

Most of you are doubtless aware of the great annoyance and pecuniary loss to which cotton manufacturers and merchants are subject, owing to the comparative frequency with which various kinds of damage, especially that generally known as mildew, occur in cotton goods. Rarely a week passes without a mildew case of greater or less importance cropping up in our midst, some firms having occasionally quite a long spell of bad luck in this respect. It seems to be the impression in certain quarters that the rage for heavy sizing, which has become so prevalent of late years, is mainly responsible for these cases of damage. I hope to show, however, that it by no means necessarily follows that heavily-sized cloth is, *ipso facto*, specially liable to become mildewed, and *vice versa*, that a so-called pure cloth (*i.e.*, one containing the smallest proportion of size which it is possible to employ) may be attacked by fungoid growths much more readily under certain conditions.

The sizing ingredients most commonly used in the process of manufacturing grey cloth are starchy matters of various kinds, such as flour, farina, &c., tallow and other fatty substances, soap, china clay, and the chlorides of zinc, calcium, and magnesium.

Small proportions of starchy, fatty, and mineral substances are almost always present in even the purest grey cloths, while the lower grades of goods contain, in addition, large quantities of weighting materials, notably china clay and deliquescent chlorides.

With the view of preventing mildew during the manufacture of the goods, and more especially afterwards, an antiseptic is generally added to the sizing mixture. Zinc chloride is the substance used almost universally among cotton manufacturers for this purpose, and is consequently found to a greater or less extent in most kinds of grey cloth, from 1 to 3 per cent. being present sometimes in heavily sized goods.

It is, perhaps, hardly necessary for me to remind you that the most favourable conditions for the formation of mildew exist when cloth free from antiseptic ingredients, but containing a large proportion of starchy matter (especially of a nitrogenous nature), is exposed to the combined action of moderate warmth and dampness.

Thirty samples of cloth were taken for the experiments, to which I shall presently refer. Some of these were selected from a large number of samples which have been sent to my laboratory for analysis during the last few years, while the remainder were obtained from well-known manufacturers specially for the purpose of this investigation. The samples in question, which are the production of 20 different manufacturers, may be regarded as representative specimens of some of the principal makes and qualities in the Manchester market.

For the sake of comparison, I also examined two samples of bleached cloth, the one of rather low quality, in which a fair amount of starchy matter was present, the other almost absolutely pure and containing only a trace of starch.

All the samples were carefully analysed by the same methods.

In the accompanying table I have recorded the results of my analyses, also the length of time necessary for the development of mildew, when the cloths were placed under conditions favourable to the growth thereof.

What I have termed "mildew tests" were made as follows:—Equal sized pieces of each sample were put into clean dry bottles; carefully measured quantities of water were then run slowly from a burette on to each piece, so as

to cause gradual and uniform absorption, and the well-corked bottles containing the damp cloth placed in an apparatus which was kept at a nearly constant temperature of 95° F. The greatest care was taken, in order to insure, as nearly as possible, the same conditions throughout the series as regards the degree of dampness, temperature, &c. The cloths were examined several times daily, so as to detect the earliest indications of fungoid growths. I may add that the experiments were repeated four times, with practically the same results each time, and all the analyses were made in duplicate, so there can be no doubt as to their accuracy.

Taking the results as a whole, I think it must be admitted that there is not so close a relationship between the composition of the different cloths and their respective

tendencies to become mildewed as might have been expected, according to preconceived ideas on the subject. I am making special reference now to the ratio between the zinc chloride and the magnesium and calcium chlorides, and also to the percentages of those ingredients in proportion to the total size present in any particular sample of cloth.

At the same time, most of the figures seem to point in the same direction, viz., that zinc chloride, if present in suitable proportion, does undoubtedly exert a preservative influence on heavily-sized cloth.

As regards the peculiar and somewhat discordant results obtained in the case of a few of the samples, I am unable to offer a really satisfactory explanation, but I think they are most probably due to the varying proportion of nitrogenous constituents in the different cloths.

NOTE ON THE APPLICATION OF ALIZARINE IN LEATHER DYEING.

BY H. KOPPELIN AND E. KNOPF, PH.D., F.R.C.

The application of alizarine to fibres other than those of vegetable origin is of comparatively recent date. Even in years ago alizarine colours on wool were practically unknown. But when, through the breaking up of the alizarine convention, alizarine was brought into the market at a low price, wool dyers began to direct their attention to this and allied colouring matters, and now large quantities of the so-called alizarine dyes are used in the production of fast shades on loose wool, stubbing, and yarn. That their superiority over other colouring matters is recognised by merchants, and probably also by the public, is revealed by the fact that special prices are sometimes quoted for alizarine dyed goods as distinct from such that are dyed with other colouring matters.

The application of the alizarines in silk dyeing is of still more recent date, but the demand for alizarine-dyed silks has hitherto been restricted to embroidery yarns, sewing silk, and stripes for trouserings. Latterly, alizarine colours have found more application in the dyeing of silk plush for seals and last fancy shades.

The usual method adopted in wool and in silk dyeing is to mordant the material first with salts of chromium, iron, aluminium or tin (for wool, chrome is principally employed), and after washing off or soaping (with silk) to dye with the colouring matter or mixture of colouring matters in such a manner that the material is entered cold or lukewarm, and the temperature of the dye-bath is gradually raised to the boil and kept at this point until the bath is exhausted. The actual formation of the colour lakes only begins at about 90° C., and is completed between this temperature and boiling point in from 20 minutes to half an hour.

For the application of alizarine or nitro-alizarine in leather dyeing, this procedure is prohibited by the fact that leather will not stand a higher temperature than about 50° C., without becoming rotten.

In order to render the production of colour lakes with alizarine on leather possible at low temperatures, we adopted a principle which had been previously employed by one of us to wool, viz., padding the material first with a solution of alizarine rendered slightly alkaline with ammonia, and then developing in solutions of alumina, chromium, or iron salts. If the pieces are dried after having been padded in the alkaline colour solution and are then printed with thickened acid or stannous chloride, a variety of white or coloured figures can be obtained on coloured grounds. Thus, if the goods padded in the ammoniacal alizarine solution and dried are printed with stannous chloride and then passed through pyrolignite of iron, an orange pattern is obtained on a violet ground.

The application of this principle of padding first with the alkaline colour solution and then developing in the mordant solution has also proved itself applicable in leather dyeing. In the practical application, the comparatively strong, slightly ammoniacal alizarine solution (or in the case of nitroalizarine, a solution of the monosodium salt) is first applied to the leather by means of a brush or pad, and the colour lake is then formed by a subsequent treatment in the mordant solution. Ordinary alum or nitrate of iron are able to precipitate a considerable amount of unchanged alizarine in the leather, and it is therefore preferable to use these salts as basic as possible.

In this manner a large variety of useful and fast alizarine shades may be produced on leather without incurring any damage to the material.

NOTE ON THE CARBONISING OF WOOL IN PRESENCE OF SILK.

BY EDMUND KNECHT, PH.D., F.R.C.

WHAT is technically known as "carbonising" consists in destroying by chemical means cotton or other vegetable matter in woollen fabrics or rags. This is effected either by passing the material through dilute sulphuric acid or aluminium chloride, and drying (wet method) or by exposing the material to an atmosphere of dry hydrochloric acid gas (dry method). By this treatment the vegetable matter becomes disintegrated, and can afterwards be beaten or shaken out as a fine powder. Thus, in the case of rags, the more valuable fibre, the wool is readily freed from its admixtures, and may be worked up again. Now silk is a more valuable fibre than wool, and since these two frequently occur together in fabrics such as umbrella cloths, silk warp Henrietta's, &c., it appeared to me desirable that a method should be forthcoming by means of which the wool might be destroyed, leaving the silk free to be worked up again into yarn.

When this problem first presented itself, it occurred to me to be a matter of impossibility to solve it, both fibres being of animal origin, and both being similarly affected by various reagents. But in trying the comparative action of acids and alkalis on the two fibres, I noticed that wool is considerably more susceptible to the action of alkalis and less susceptible to the action of acids than silk is. Thus I found it possible by boiling the mixed fabric with very dilute alkali to destroy the wool and leave the silk comparatively strong. But a safer method is based upon the difference in the behaviour of the two fibres towards pure water at high temperatures. If the mixed fabric (say, consisting of silk warp and woollen weft) is heated with water for some time to about 130° C., it will be found that the wool is so changed that it can be readily rubbed to a powder, while the silk remains comparatively unacted upon. My experiments were carried out in sealed glass tubes. The application of the principle on the large scale should not present any difficulties, and the process might find some industrial application either in the regeneration of silks from waste or in the textile industries.

NOTE ON THE FORMATION AND DIRECT FIXATION OF INSOLUBLE TARTRAZINE ON ANIMAL FIBRE.

BY EDMUND KNECHT, PH.D., F.R.C.

THE colouring matter, which is known as *tartrazine*, is the only commercial representative of an interesting class of dyestuffs discovered by Ziegler, and known as the osazone colouring matters. They are formed by the action of primary aromatic hydrazines or their sulphonic acids on

dis-ketones containing the group $\begin{array}{c} \text{CO} \\ | \\ \text{C} \\ | \\ \text{CO} \end{array}$ like benzil, phenanthrenequinone, &c.

Commercial tartrazine is obtained by acting upon one molecule of dioxystartaric acid with two molecules of phenylhydrazine para-sulphonic acid in hydrochloric acid solution. Its composition is represented by the formula—

In wool-dyeing tartrazine is of great value on account of its fastness to light. In this respect it ranks with indigo as one of the fastest dyes we possess. Towards milling, however, tartrazine is not absolutely fast, and it was with a view of producing a yellow colour which was absolutely fast to light and milling that I endeavoured to fix the unsulphonated colour on the fibre.

If dioxytartaric acid and phenylhydrazine are mixed in hydrochloric acid solution in the proportion of one molecule of the former to two of the latter, no change takes place at first, but the liquid soon becomes yellow and after some time an orange yellow precipitate begins to settle. The reaction takes place more rapidly on boiling. The insoluble yellow precipitate is the elementary tartrazine—

By immersing silk or wool in a solution prepared as described and raising the temperature gradually to the boil, I found that the whole of the colour, instead of being precipitated in the bath, became assimilated by the fibre. The colours thus obtained are not so bright as those obtained with commercial tartrazine.

Contrary to my expectations, the insoluble colouring matter showed itself to be less fast to soap than the ordinary sulphonated product. Experiments which were made with a view of fixing insoluble tartrazine on cotton by dyeing were unsuccessful, but probably the fixation of the colour on the fibre in calico-printing would take place in presence of an organic acid. It may also be fixed according to a patent recently taken out by a continental firm of colour makers, by printing insoluble tartrazine, chromium acetate and thickening, and then steaming. The colour thus obtained is said to be characterised by its great fastness.

ON A RAPID METHOD OF SOLUTION IN THE COLD.

BY J. BERNARD COLEMAN, A.R.C.S., F.I.C., F.C.S.,
UNIVERSITY COLLEGE, NOTTINGHAM.

SOME time ago, wishing to ascertain the solubility of a salt in water, I conducted a few experiments to determine the time required by different salts to form a saturated solution in cold water. The first method employed was as follows:—The salt, coarsely powdered, was enclosed in a fine muslin bag, and suspended in the *upper* part of a vessel filled with distilled water: in this way, the water in contact with the salt becomes nearly saturated, and falls to the bottom of the vessel, fresh water, or water not so fully saturated, taking its place; thus the process of solution is continuous.

In the experiments recorded in the next page, on the salts $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ and KClO_3 , respectively (Method 1) it will be seen that at least 12 hours, probably more, are required for complete solution. This method is therefore tedious, and cannot be performed in one working day.

The discrepancies noticed in this series, and also in the second series (Method 2) are due to the experiments sometimes lasting throughout the night, in which case the percentage obtained would be from a quantity of the solution taken out in the morning, thus the percentage would be low, as the *mean* temperature during the night was low. On the other hand, if the solution were taken at night, the percentage would be high, since the *mean* temperature of the solution during the day was higher. In Method 3 the temperature was constant.

In all cases the percentage of salt dissolved was obtained by taking out a quantity of the liquid by means of a pipette, filtering, rejecting the first portion of the filtrate, the remainder of the filtrate being received in a weighed stoppered bottle and then weighed. From this solution the weight of $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ was obtained by estimation as CuO and calculation into $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$. In the case of the KClO_3 it was evaporated to dryness in a tared dish, dried at 100°C . and weighed as KClO_3 .

The next method (Method 2) employed was a modification of the above. In addition to keeping the solid near the surface of the liquid, a vigorous shaking took place about every half-hour. The salt, coarsely powdered as before, was put into a stoppered cylinder, one-half full of water; a vigorous shaking was applied, and the cylinder inclined, so that the salt remained near the surface of the water in the cylinder. As mentioned, the shaking was repeated about every half-hour, and the cylinder inclined as before. On reference to the table (Method 2), it will be that, although the method is more rapid than the previous one, it is not probable that solution would be complete in the case of the $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ in much less than 10 hours.

Both the preceding methods are too long for, say, ascertaining the solubility of a salt in a solvent at a *fixed* temperature; in fact, it is difficult to regulate the temperature for so long a period without slight variations.

Eventually I found that, by simply passing a current of air through the coarsely powdered solid, suspended in water, complete solution could be obtained, in some cases in the space of 15 minutes, and in most cases before the expiration of an hour.

The process is conducted as follows: the solid is put into a glass cylinder half filled with distilled water. The mouth of the jar is tightly stoppered with an india-rubber cork, through which pass two glass tubes. One of the glass tubes has inserted in the upper end a plug of cotton wool to keep out dust, the lower end is drawn out a little and bent, as shown in the Figure, and passes to the bottom of the cylinder; the other tube just passes through the cork. Before use the cylinder is surrounded by a vessel containing water of the temperature at which the solubility of the solid is to be tested; the short tube is then connected with a water aspirator. A continuous current of air thus passes through, forcing the solid through the liquid in a circuitous path. In the experiments recorded in the table (Method 3)

$\text{Cu}_2\text{SO}_4 \cdot 5 \text{H}_2\text{O}$					KClO_3

	2 hours	16·5	25·55	2 hours	16·5	5·81

* Aspirator stopped for 1½ hours.

the $\text{CuSO}_4 \cdot 5 \text{H}_2\text{O}$ and KClO_3 in solution, were estimated in the manner described above; it will be seen that 15 minutes sufficed for complete solution of the KClO_3 and

half an hour for that of the $\text{CuSO}_4 \cdot 5 \text{H}_2\text{O}$. Probably an hour would be the limit of time required for the complete solution of any salt.

For the sake of comparison, I contrasted the last results with the results tabulated in Method 1, i.e. boiling up the coarsely powdered solid with water, and rapidly cooling down to the required temperature with continuous stirring. Although in this method there is the fear of supersaturation occurring, still the results agree very closely with Method 3.

The advantages of the aspiration method consists, (1) in the comparatively short time required for solution; (2) no expensive apparatus, such as water motors and revolving mechanical agitators, is required. In places where high-pressure water is not available, steam may be substituted by simply attaching a flask of boiling water to the aspirator, and it will be found to answer as well.

The aspirator used in these experiments is that known as Geissler's.

The objections to this process are, (1) the solution may be supersaturated by the air, causing evaporation during its

passage through the liquid; (2) that readily oxidisable substances are excluded.

The first objection may be overcome by passing the air through water before passing it through the body undergoing solution; thus rendering the air moist.

The second difficulty can usually be met by employing coal-gas in place of air, care being taken that the oxygen and carbon dioxide present in the coal-gas are thoroughly absorbed by alkaline potassium pyrogallate.

I determined the solubility of $\text{FeSO}_4 \cdot 7 \text{H}_2\text{O}$ in the following manner as a test case.

The coal-gas was passed through three U-tubes, with 9-in. limbs, filled with pumice soaked in alkaline potassium pyrogallate. This procedure was found to have removed all the carbon dioxide and oxygen in the coal-gas.

The gas was then passed through the coarsely powdered $\text{FeSO}_4 \cdot 7 \text{H}_2\text{O}$ in the manner described (Method 3).

The following results were obtained with two estimations:—

$\text{FeSO}_4 \cdot 7 \text{H}_2\text{O}$.

Time.	Temperature.	Percentage.	Per Cent. of Fe^{++} Salt before Aspiration.	Per Cent. of Fe^{++} Salt after Aspiration.
Min.	° C.			
30	15	33·76	99·07	99·00
30	15	33·75	99·07	99·03

The above examples show that the process is also useful for oxidisable substances, since the amount of iron oxidised during the passage of the gas increased 0·07 per cent. only.

The percentage of ferrous iron in the original salt (99·07), and also after aspiration (99·01), was determined by the bichromate method.

I have to thank Messrs. Smith, Halls, and Adams, students in the chemical laboratory, for considerable analytical help.

ON THE REVISION OF CONSTANTS EMPLOYED IN THE ANALYSIS OF FATS AND OILS.

BY R. T. THOMSON, F.I.C., AND H. BALLANTYNE.

PART II.

IN our previous paper on this subject (see this Journal, Vol. IX., p. 588), we stated that our object was to revise the constants of various oils, and to record these for each individual oil, and not only for each class of oil. Several of the oils for which we gave constants formerly have been mislaid, and one or two have changed somewhat by exposure to light and being insufficiently stoppered, according to the description already published by one of us (see article on "The Effect of Exposure under Certain Conditions upon some Constants of Oils," by H. Ballantyne, in this volume, p. 29). In the accompanying table of "constants in oil analysis" will be found that portion of our results which may fairly be regarded as useful in oil analysis. In it are included figures for fresh specimens of olive and other oils, and the old and new results of the oils formerly partially examined. We have also stated the percentage of free (oleic) acid in each sample, and although this cannot be looked upon as a constant, yet it serves a purpose in indicating to some extent the condition of the oil, and shows how little, if any, a high free acidity affects the results of analysis.

Iodine Absorption.—The first column in the table contains the iodine absorptions, and there is little to add to our remarks in Vol. IX., p. 587. It was there noted that the

variation in iodine absorption for different olive oils was greater than usually stated. Since then we have found one half a per cent. higher still, so that the iodine value ranges from that of Gioja (79 per cent.) to that of Mogadore olive oil (86.9 per cent.). We have also examined a rape oil with an iodine absorbing power of only 99.1 per cent., which is the lowest figure we have yet obtained for that oil. The sample of rape oil given in our former table as 110.1 should have been actually printed 10 per cent. less; so that the highest iodine absorption for rape oil stands at 105.6 per cent.

Potash Neutralising Power.—It is perhaps worthy of note that the figures in our table respecting olive oil do not represent such a great variation between each individual oil as those given by Koettstorfer, Stoddart, and Valenta, but they are in close accord with those of Archbutt. With rape oil also the difference in potash neutralising power agrees with Archbutt's results, and is not so marked as that stated by other observers. Of the five specimens of linseed oil examined by us, the limits lie between 19.00 and 19.28, while those of nine specimens tested by other observers, and recorded by Allen, vary from 18.74 to 19.52. With our four different specimens of seal oil there is only a difference of 18.93 to 19.37, while Stoddart and Deering, testing an equal number of samples, show differences to the extent of 18.90 to 19.60. In all cases, while our iodine absorptions have, on the whole, shown wider variations, our results of potash neutralising power have exhibited narrower differences, for oils of the same class, than other observers.

Unsaponifiable Matter.—A knowledge of the percentage of unsaponifiable matter in genuine oils is of great importance, as on this depends how much of that ingredient must be reckoned as mineral or rosin oil in an adulterated sample. Hitherto we have had to be content with Allen's quite correct statement that the proportion present in oils and fats is not more than 1.5 per cent., and usually much less. It is quite possible, however, that much greater use might be made of the unsaponifiable matter in detecting adulterants. It will be observed in the table of constants that olive, refined cotton-seed, unrefined arachis, and linseed oils contain about the same proportion of unsaponifiable matter, and therefore the determination of that constituent in a sample, say, of olive oil, would not serve to show any adulteration with either of the other three oils. But the presence of a considerable proportion of rape oil would tend to have a lowering effect on the percentage of unsaponifiable matter. Again, in marine oils it is a remarkable fact that seal oils contain only about one-third of that contained in whale, cod, and menhaden oils; therefore, if an abnormally high percentage of unsaponifiable matter (not due to mineral or rosin oil) were obtained in seal oil, there would be a presumption at least of adulteration with menhaden or other fish oil. Of course more determinations of "constants" of various qualities of these oils may be necessary to establish such distinctions on a firm basis. But, in the meantime, the analysis of oils cannot be made with such scientific accuracy as to warrant us to dispense with even the slightest guide to the determination of their purity.

It may be noted in passing that in the estimation of the unsaponifiable matter, if the ethereal layer is equal in volume to the lower layer of soap solution, four-fifths or 80 per cent. of the ingredient may be determined by one extraction. The other fifth may be allowed for by adding one-fourth of that obtained by the first extraction, or by a second extraction, especially if the proportion expected is large.

Of the *specific gravities* of the various samples there is nothing special to remark.

Specific Temperature Reaction.—This is simply a modified way of recording the results of Maumene's temperature reaction with strong sulphuric acid. Broadly stated, and divested of all the little necessary precautions, Maumene's test shows the rise in temperature by mixing together 50 grms. of the oil and 10 cc. of sulphuric acid. Various observers have shown that a slight difference in the strength of the acid affects the rise in temperature very considerably, so that a careful taking of the density, or a gravimetric or volumetric estimation has been recommended. The density

and gravimetric test may both be objected to on the ground that their accuracy would be impaired should the acid contain any sulphates of metals, but no such objection can be urged against the volumetric method. But a much simpler test even than the latter may be applied to the acid, and on this is based what we have named the specific temperature reaction. It simply consists in mixing 50 grms. of water with 10 cc. of the sulphuric acid (each at 20° C.), and registering the highest temperature reached. The amount of water is best measured from a pipette at 15.5° C., and the sulphuric acid should be run in from a pipette which will deliver the 10 cc. in one minute. During the addition the mixture should be vigorously stirred with the thermometer, and the highest temperature reached rapidly read off, as it only remains constant for a few seconds. Care should be taken in measuring the water, as a material error may come in if a little less water should be employed. For instance, one gramme less of water will give a higher reading of 0.8° C. The oil being tested in precisely the same way, it is only necessary to divide the rise in temperature obtained with water into that obtained by the oil under examination. The answer is the specific temperature reaction compared with water as 1, which is the customary mode of expression; but in our table we have recorded the results compared with water as 100, in order to dispense with decimals.

In applying the test some precautions are necessary, and a few details in manipulation must be observed. The oils must be carefully weighed, and the acid added to them exactly as with water, except that even more vigorous stirring is necessary during and after the addition of acid. In all the experiments made in this way no abnormal rise in temperature by local superheating was ever observed. The rise was fairly steady up to the highest point, at which it remained constant for 50 or 60 seconds. In the cases of

linseed, cod, seal, and menhaden oils the tests had to be made with a mixture of 20 grms. of these oils and 30 of olive oil of a known specific temperature reaction.

The tests were performed in a thin beaker surrounded with cotton wool, but it was found that the shape of the beaker had a considerable influence on the rise in temperature. Thus, with sulphuric acid of 96.8 per cent. in a beaker 3 in. high and 2 in. wide, water showed a rise of 41.7°, while Malaga olive oil gave a rise of 39° C. In a beaker 4 in. in height and 2 in. in width the water recorded 43.7°, and the same oil 41°, being a difference of 2° in each case. When the specific temperature reaction of the oil is calculated out, we obtain 93.5 and 93.8 for the respective beakers; and such results are as close as need be. From these data we gain the valuable precaution that the oil or oils to be examined must be tested in the identical vessels in which the test with the water is made. In Maumene's original method of testing oils no account whatever is taken of using different vessels, and by it there is no means by which allowance can be made for a fresh beaker when the first one is broken; unless indeed a few beakers are always kept which have been tested against each other. By adopting the specific temperature test all that is necessary is to standardise a new beaker with water and sulphuric acid, and make the experiments in it with the oils to be tested, using the new temperature reaction with water as the standard.

It is a well-known fact that acids of different strength give widely different results in taking Maumene's temperature reaction of oils, and therefore some experiments were made to ascertain if this also affected the specific temperature reaction. Three different strengths of sulphuric acid were used, and the results of their treatment with water and several oils are given in the following table:—

TABLE SHOWING THE RISE IN TEMPERATURE AND SPECIFIC TEMPERATURE REACTION WITH SULPHURIC ACID OF DIFFERENT STRENGTHS.

Sample.	H ₂ SO ₄ of 95.4 per Cent.		H ₂ SO ₄ of 96.8 per Cent.		H ₂ SO ₄ of 99 per Cent.	
	Rise in Temperature °C.	Specific Temperature Reaction.	Rise in Temperature °C.	Specific Temperature Reaction.	Rise in Temperature °C.	Specific Temperature Reaction.
Water	38.6	100	41.4	100	47.5	100
	50.7	95	50.4	95	44.8	96
Olive oil	39.0	94	43.8	94
	34.0	88	38.4	92	41.2	95
Rape oil	39.0	127	58.0	124
Castor oil	34.0	88	37.0	89
Linseed oil	101.5	270	125.2	269

An examination of this table shows how even a little difference in the strength of the sulphuric acid may largely affect the temperature test as usually reported; while the specific temperature reaction is influenced only to a comparatively small extent. In one case with an olive oil the strongest acid shows a considerable discrepancy when the result is compared with that of the weakest, but nothing like the difference brought out by a comparison of the rise in temperature alone. The vast superiority of the specific temperature reaction to the usual method of recording results is most clearly shown with linseed oil, which indicates a difference of nearly 20 in 125 between the weakest and strongest acid, when the specific temperature reaction only exhibits a variation of 1 in 270. To obviate the obtaining of abnormal results, due to difference in strength of sulphuric acids, we use an acid which gives with water a rise of from 42 to 44°, when the experiment is conducted in a beaker about 4 in. in height and 2 in. in width. Sulphuric acid conforming to this test will contain from 95.5 to 97 per cent. of real sulphuric acid.

It may perhaps be as well to note that the proportion of acid to oil or water must in no case be altered, for as already explained 1 gram too little water means a higher rise in temperature by about 0.8°. With oils, on the other hand, the effect is usually to give a considerably less rise, so that by inattention to exact weighing and measurement, a double error may easily be introduced.

When 50 grms. of the oil cannot be spared, the quantities of oil and sulphuric acid may be halved, and the results compared with those obtained with half quantities of water and acid. In such circumstances the specific temperature reactions are precisely the same as those quoted in the table for the double quantities, but the reading of the thermometer must be done more sharply in the former than the latter case.

It is almost unnecessary now to point out that this reaction may be utilised as a valuable adjunct to the iodine absorption and other constants, for the detection of such oils as rape and cotton-seeds, in olive oil, and for other analyses which will suggest themselves to all chemists.

As a general rule, an oil possessing a high iodine absorption has also a high specific temperature reaction, but the rise in the latter is not always directly as that in the former. The reason the specific temperature reaction cannot be relied on with the same assurance as the iodine absorption is because it shows in some cases large variations for the same class of oil. This defect is not noticeable in any of the olive, cotton-seed, castor, or seal oils we have examined, but some of the figures obtained from arachis, rape, and linseed oils are extremely and unexplainably different. Thus, rape oils vary from 125 to 144, arachis from 105 to 137, and linseed no less than from 270 to 349; and yet all the other constants agree within reasonable limits. In spite of these defects, and in consideration of the state of knowledge with regard to the chemical constitution of oils, the specific temperature test may be relied on, when judiciously used, as a valuable constant in the analysis of oils.

Valenta's Test.—Some seven years ago this test was introduced by Valenta, and, as is well known, consists in beating equal volumes of the oil and of glacial acetic acid (sp. gr. 1.0562) until perfect solution is obtained, and then observing at what temperature turbidity appears. In his second volume on "Commercial Organic Analysis," Allen states that a little difference in the strength of the acetic acid does not matter, and suggests that certain variations in the turbidity temperature of different specimens of the same kind of oil is due to a difference in the proportion of free fatty acids contained in them. In compiling the following table, which contains the results of our experiments, we have kept these two suggestions in view.

TABLE SHOWING THE TURBIDITY TEMPERATURE OF VARIOUS OILS BY VALENTA'S TEST.

Name of Oil.	Free (Glacial) Acid per Cent.	Turbidity Temperature (°C.) with Glacial Acetic Acid of —		
		Sp. Gr. 1051.2.	Sp. Gr. 1055.2.	Sp. Gr. 1056.2.
Olive (Gioja)	9.42	65	80	91
Olive (Gioja) free acid removed.	None	87
Olive (Syrian)	23.88	42
Olive	5.19	78	96	..
	3.86	85	100	111
Arachis (commercial) ..	6.20	76	92	112
" (French refined)	6.62	96	114	Not completely dissolved.
Rape	2.43	110	Not completely dissolved.	"
	1.54	105	"	"
Linseed	7.76	61	78	90
" (Baltic)	3.74	42	59	71
" (East India) ...	7.79	57
" (River Plate) ...	1.21	56

An inspection of the above table shows that ascertained facts fully bear out Allen's theory with regard to the decided influence on Valenta's test of the presence of varying proportions of free fatty acids in oils. This is well illustrated in the case of the Gioja olive oil, which was tested as first obtained, and after removal of the free acid by agitation with caustic potash solution. It will also be observed that with all the oils given on the table, the turbidity temperature is high when little free acid is present, and becomes lower as the proportion of free acid rises. The difference of 22° between the results obtained with the acid and the acid-free Gioja oil shows that each per cent. of free fatty acids lowers the turbidity temperature by 2.33°.

and this correction might be applied to get the "constant" of the acid-free oil. If we make these allowances for the other three olive oils on the table, we find the corrected temperatures would be 97°, 90°, and 94° respectively, when the strongest acetic acid is employed.

The influence of the free acids contained in arachis and linseed oils would appear to be much greater, and those of rape oil considerably less, than those in olive oil. Thus each class of oil would require a special correction for free fatty acids, and when we come to mixtures of oils their composition would actually require to be known before a correct turbidity temperature could be calculated. These facts alone are sufficient to show the hopeless unreliability of Valenta's test.

It is a noticeable fact that the statement generally made with regard to the insolubility of rape oil in glacial acetic acid is true only so far as the acid recommended by Valenta and the absolute acid of Oudemann's table are concerned. The highest strength of acid given on our table dissolves rape oil containing about 2½ per cent. of free acid at 110°, and would probably dissolve the acid-free oil at 115° or 116°.

It will also be seen from the table that a comparatively slight variation in the strength of the acetic acid contributes very seriously to the obtaining of discordant results. Thus a difference of 0.1 in the specific gravity means a variation of about 1.5 in the turbidity temperature; and one accustomed to taking specific gravities of strong acids knows well that the highest skill in manipulation is necessary to take densities within such close limits.

Taking all these facts into consideration, we are forced to the conclusion that Valenta's test is surrounded with too many conditions to be of any practical value in the general analysis of oils.

A few words of explanation must here be given with reference to the strengths of the acetic acid used in the above tests. The strongest acid (sp. gr. 1054.2) was purchased as pure glacial acetic acid, and we were much struck with the low specific gravity it showed as compared with the lowest (1055.3) for glacial acetic acid in Oudemann's table. The strength of this acid was determined by making several acidimetric titrations with caustic soda solution, which had been standardised against normal sulphuric acid. In every case phenolphthalein was employed as indicator, as it is the only one which gives a perfectly satisfactory end reaction with acetic acid. The normal sulphuric acid was in its turn carefully tested both by volumetric tests with pure sodium carbonate and gravimetric determinations as barium sulphate.

The other two acetic acids (sp. grs. 1055.2 and 1056.2) were prepared from the strongest one by mixing together known quantities of the acid and water. These also were titrated, and the results obtained agreed well with the proportions added together. The following are the average results of the various tests, most of which agreed exactly, while the others came within very narrow limits.

TABLE SHOWING STRENGTHS OF GLACIAL ACETIC ACID.

Specific Gravity of the Acid at 15° C. (Water at 15° = 1.000).	Per Cent. by Weight of Real Acetic Acid (C ₂ H ₃ O ₂).
1054.2	99.1
1055.2	98.5
1056.2	97.9

It may be mentioned that the specific gravities at 15.5° were exactly the same as these. From these results it is apparent that chemically pure acetic acid will possess a specific gravity of about 1.053, and that what we now look upon as glacial acetic acid actually contains 1½ per cent. of water. Applying the well-known tests for water in glacial acetic acid, we found that the first-mentioned acid in the foregoing table is very easily miscible with an equal volume

TABLE OF CONSTANTS, &c. USED IN THE ANALYSIS OF OILS.
